877 Asthma Mortality - Illinois, 1979-1994

## Update: Trends in AIDS Incidence - United States, 1996

Provisional surveillance data about acquired immunodeficiency syndrome (AIDS) for the first 6 months of 1996 indicated a decrease in deaths among persons with AIDS, attributed primarily to the effect of antiretroviral therapies on the survival of persons infected with human immunodeficiency virus (HIV) (1). This report describes a decline in AIDS incidence during 1996 compared with 1995 and the continued decline in AIDS deaths; the findings indicate that HIV therapies are having a widespread beneficial impact on the rate of HIV disease progression in the United States.*

Cumulative AIDS cases among persons aged $\geq 13$ years reported to CDC through June 1997 from the 50 states, the District of Columbia, and the U.S. territories were analyzed by sex, age, race/ethnicity, and mode of risk/exposure ${ }^{\dagger}$ (2). Estimates of AIDS incidence and deaths were adjusted for delays in reporting. For analyses by risk/exposure, estimates were adjusted for the anticipated reclassification of cases initially reported without an HIV risk/exposure (2). To adjust for the 1993 expansion of the AIDS reporting criteria ${ }^{\S}$, estimates of the incidence of AIDS-opportunistic illnesses (AIDS-Ols) were calculated from the sum of cases reported with an AIDS-Ol and cases with estimated dates of diagnosis of an AIDS-OI that were reported based only on immunologic criteria (2). AIDS-Ol incidence was estimated quarterly through December 1996 (the most recent period for which reliable estimates were available). Deaths among persons with AIDS were identified by review of medical records and death certificates and represent both deaths from HIV-related and other causes. AIDS prevalence was estimated as the cumulative incidence of AIDS based on the 1993 expanded AIDS case criteria minus cumulative deaths. Populations with <500 estimated cases were excluded because the estimates of annual percentage change from 1995 to 1996 in AIDS-OI incidence, deaths, and prevalence are not reliable.

[^0]
## AIDS Incidence - Continued

## AIDS-OI Incidence

During 1996, AIDS-Ols were diagnosed in an estimated 56,730 persons, a decline of $6 \%$ compared with 1995 (Figure 1). This represents the first calendar year during which AIDS-OI incidence overall did not increase in the United States.

From 1995 to 1996, AIDS-OI incidence declined in all four geographic regions of the United States (West [12\%], Midwest [10\%], Northeast [8\%], and South [1\%])". AIDS-OI incidence decreased in all 5 -year age groups; men; non-Hispanic whites and Hispanics; men who have sex with men (MSM); injecting-drug users (IDUs); and men who reported both of these exposures (MSM-IDUs) (Table 1). The largest proportionate declines occurred among non-Hispanic white MSM (Figure 2) and non-Hispanic white and black MSM-IDUs (Table 2). AIDS-OI incidence leveled among non-Hispanic blacks. The greatest proportionate increases in AIDS-OI incidence occurred among non-Hispanic black men (19\%), Hispanic men (13\%), and non-Hispanic black women (12\%) who had heterosexual risk/exposures (Table 2).

| Total** | 60,620 | 56,730 | - 6 | 50,140 | 38,780 | -23 |

*Estimates are presented rounded to the nearest 10 because they do not represent exact counts of persons with AIDS-Ols but are estimates that are approximately $\pm 3 \%$ of the true value.
${ }^{\dagger}$ Numbers for races other than black and white were too small for meaningful analysis. Persons of Hispanic origin may be of any race.
${ }^{\S}$ Men who have sex with men.
§Injecting-drug user.
** Includes persons aged $\geq 13$ years with hemophilia/coagulation disorders, transfusion recipients, or with other or no risks reported.

From 1995 to 1996, annual AIDS incidence changed abruptly compared with the magnitude and direction of the average annual changes in AIDS-OI incidence during 1992-1995. During these years, AIDS-OI incidence increased but was characterized by a slowing in the growth of the epidemic overall (average annual change from 1992 to 1995 was $2 \%$ ) (1,2). The magnitude and/or the direction of the average annual change in AIDS-OI incidence from 1992 to 1995 was substantially different from the change from 1995 to 1996 among men ( $1 \%$ versus $-8 \%$ ) and women ( $10 \%$ versus $2 \%$ ); whites ( $-2 \%$ versus $-13 \%$ ), non-Hispanic blacks ( $7 \%$ versus 0 ), and Hispanics ( $4 \%$ versus $-5 \%$ ); MSM ( $-1 \%$ versus $-11 \%$ ), men and women IDUs ( $3 \%$ versus $-6 \%$ and $5 \%$ versus $-4 \%$, respectively), and MSM-IDUs ( $-3 \%$ versus $-15 \%$ ).

## Deaths Among Persons Reported with AIDS

Deaths among persons reported with AIDS declined 23\% in 1996 compared with 1995, with the largest declines occurring during the last three quarters of 1996 (Figure 1). From 1995 to 1996, deaths declined in all four geographic regions (West

## AIDS Incidence - Continued

[33\%], Midwest [25\%], Northeast [22\%], and South [19\%]); among men and women; among all racial/ethnic groups; and in all risk/exposure categories (Table 1).

## AIDS Prevalence

Approximately 235,470 persons in whom AIDS has been diagnosed are still living, and from 1995 to 1996, the prevalence of AIDS increased 11\% (Table 3). MSM accounted for the largest proportion (48\%) of persons with AIDS, and the largest proportionate increases in prevalence occurred among men and women who acquired AIDS through heterosexual contact ( $28 \%$ and $23 \%$, respectively), the only risk/exposure category that experienced increases in AIDS-OI incidence.
Reported by: State and local health depts. Div of HIV/AIDS Prevention-Surveillance and Epidemiology, National Center for HIV, STD, and TB Prevention, CDC.
Editorial Note: The findings in this report document the first overall decline in the annual incidence of AIDS-Ols in the United States. Concurrently, annual deaths among persons aged $\geq 13$ years reported with AIDS also have decreased. Temporal trends in AIDS cases and deaths are the result of changes in the rate of new HIV infections, AIDS diagnoses resulting from progression of HIV disease to AIDS, and deaths of HIVinfected persons. The declines in AIDS-OI incidence and deaths reflect the impact of both HIV prevention efforts and the use of antiretroviral therapies and AIDS-OI prophylaxis.

During 1996, AIDS-OI incidence declined for almost all populations and in all regions of the country, and deaths declined substantially (23\%) compared with 1995. The actual decline in AIDS-OI incidence is probably greater than the estimates in this report because there are insufficient longitudinal clinical data to model the impact of the newly available antiretroviral therapies on AIDS-OI incidence. However, the 1996 AIDS surveillance data are consistent with reports that recent improvements in HIV

## AIDS Incidence - Continued

care are preventing or delaying the onset of AIDS-OI and deaths among many populations of HIV-infected persons (3). Recent declines in AIDS incidence also have been reported in several western European countries and have been attributed to widespread use of combination antiretroviral therapies (4).

Data from CDC's Adult/Adolescent Spectrum of Disease (ASD) (5) project indicate that an increasing proportion of HIV-infected persons are receiving combination antiretroviral therapy. Among HIV-infected persons observed in clinical care in ASD during 1995-1996, the prescribed use of combination antiretroviral therapy increased from $24 \%$ of 5027 persons in the second half of 1995 to $65 \%$ of 2973 persons in the second half of 1996 (CDC, unpublished data, 1997). Use of these therapies is expected to increase because revised HIV treatment guidelines recommend earlier initiation of combination antiretroviral therapy in HIV-infected persons without AIDS-defining conditions (6).

Ensuring timely access to HIV-care services for HIV-infected persons remains important because in many persons HIV infection is not diagnosed until AIDS is diagnosed (7). To enable HIV-infected persons to benefit from treatment advances, HIV counseling and testing programs in screening and health-care settings must better facilitate early diagnosis of HIV infection and ensure that HIV-infected persons have access to care and treatment services.

Despite the decreases in AIDS-OI incidence and deaths in 1996, AIDS-OI incidence remained high, and HIV infection remained a leading cause of death among persons aged $25-44$ years ( 8 ). AIDS-OI incidence continued to increase among persons who were infected through heterosexual contact. Until effective vaccines are developed, continued emphasis on behavioral risk-reduction and other prevention strategies targeted to these populations is the most effective way to reduce HIV infections.

The 1996 AIDS surveillance trends illustrate how surveillance data are now affected by both patterns of HIV incidence and HIV treatment advances. In comparison, surveillance based on a diagnosis of HIV infection is not affected by changes in the progression of HIV disease. CDC supports both HIV and AIDS surveillance in 30 states. Among these states, the number of prevalent HIV and AIDS cases combined is approximately 2.5 times greater than the number of prevalent AIDS cases alone (1,2). HIV/AIDS surveillance programs in these states provide a more timely measure of emerging patterns of HIV transmission, a more complete estimate of the number of persons with HIV infection and disease, and a better mechanism to evaluate access to HIV testing and medical and prevention services than AIDS surveillance alone (9).

Although AIDS surveillance continues to be essential for understanding reasons for the lack of timely access to HIV testing and care and the failure of treatment regimens to delay HIV disease progression, HIV surveillance is becoming increasingly important as more infected persons receive effective antiretroviral therapy. In June 1997, the Council of State and Territorial Epidemiologists (CSTE) recommended that all states implement HIV case reporting by name from health-care providers and laboratories (10). The Association of State and Territorial Health Officers has provisionally endorsed the CSTE recommendation pending a vote of its full membership. CDC recently provided additional resources to state and local surveillance programs that plan to or are conducting HIV case surveillance in addition to AIDS surveillance.

All states and territories should conduct HIV case surveillance as an extension of their AIDS Surveillance programs, and CDC is developing HIV surveillance policy and

## AIDS Incidence - Continued

technical guidance to assist all states and territories to conduct HIV/AIDS case surveillance. CDC and CSTE recently convened a consultation** to discuss the objectives and methods of conducting HIV/AIDS case surveillance. CDC will continue to foster a collaborative approach among public health authorities, health-care providers, and the community to meet their information needs and to ensure the confidentiality of HIV/AIDS surveillance data.

## Impact of Promotion of the Great American Smokeout and Availability of Over-the-Counter Nicotine Medications, 1996

The 1996 Great American Smokeout (GASO), sponsored by the American Cancer Society (ACS), was held on November 21 and included a national promotional campaign in collaboration with a distributor of over-the-counter (OTC) nicotine medications. The 1996 GASO was the first to use a national promotion that included paid advertising of the GASO through television, magazines, and newspapers; direct-toconsumer promotions; and educational activities about GASO in retail stores that sell OTC nicotine medications. ${ }^{*}$ To estimate the impact of this promotional partnership between ACS and a distributor of OTC nicotine medications on smoking-cessation

[^3]GASO Promotion and OTC Nicotine Medications - Continued
activity, the collaborators ${ }^{\dagger}$ analyzed data from three sources. This report summarizes the findings, which suggest that the promotional campaign, combined with OTC availability of nicotine medications, encouraged smoking-cessation activity.

The 1996 GASO promotion encouraged quitting in general and did not promote any specific brand of nicotine medications; the focus of the promotion was on quitting on the day of the GASO, November 21. In addition, brand-specific nicotine medication advertising largely did not change during the 1996 promotion. To estimate the number of persons exposed to television promotions of the GASO, A.C. Nielsen's National TV Index Service assessed the number of times viewers in the study sample were exposed to an advertisement (1); such exposures are known as impressions.

To estimate awareness of and participation in the GASO, including efforts to quit smoking on the day of the GASO, ACS commissioned Lieberman Research, Inc., to conduct random-digit-dialed telephone surveys in 1995 and 1996. In 1995, a survey of 5504 adults aged $\geq 21$ years, including 1366 smokers, was conducted from November 17 through November 26. The nationally representative sample comprised $\geq 100$ interviews in each of 48 states; the District of Columbia; Long Island, New York; and the cities of Philadelphia, Pennsylvania, and New York, New York. Data were weighted to produce national estimates. In 1996, a nationwide survey of 983 adults aged $\geq 21$ years was conducted from November 22 through November 26. Smokers were oversampled ( $n=379$ ), and the data were weighted to produce nationally representative estimates (2). Respondents in the 1995 and 1996 surveys were asked, "On the day of the Great American Smokeout, which of these things did you do: not smoke cigarettes at all; cut down the number of cigarettes you usually smoke; or smoke as much as usual?"

Retail sales of OTC nicotine medications (i.e., Nicorette ${ }^{\circledR}$ nicotine chewing gum, NicoDerm ${ }^{\circledR} \mathrm{CQ}^{\mathrm{TM}}$ nicotine patches, and Nicotro ${ }^{\circledR}{ }^{\circledR}$ nicotine patches $)^{\S}$ in 1996 were estimated by A.C. Nielsen's InFact Service, which tallies purchases entered the cash registers of food, drug, and mass merchandisers by electronic Universal Product Code (UPC) scanner. Data were collected from a nationally representative sample of 10,000 outlets located primarily in the top 50 major markets. Purchases from retail outlets without scanner technology were estimated by a sample of those stores. The sample was then weighted to estimate total unit purchases from all outlets. The resulting figures underestimate actual sales (by comparison with factory shipments); therefore, this analysis assumes a $5 \%$ underestimation of sales. Projected sales of all three OTC nicotine medications were adjusted to account for underestimation. The baseline period was defined as the 4 -week period ending November 2, and the GASO promotion period was the 4 -week period ending November 30.

The National TV Index Service reported that the paid advertising specifically for the GASO reached 122.1 million adults aged $\geq 18$ years an average of 2.9 times during the 3 weeks before and the week of the GASO, representing a total of approximately 354 million television impressions nationally. Assuming equal distribution of these impressions among smokers and nonsmokers, an estimated 30.5 million smokers ( $64 \%$ of all U.S. smokers) (2) were exposed to GASO promotions.

[^4]
## GASO Promotion and OTC Nicotine Medications - Continued

Responses to the 1995 and 1996 Lieberman surveys were compared to determine whether GASO-related smoking-reduction and smoking-cessation rates changed from 1995 to 1996. During this period, the percentage of respondents who initiated any action during the GASO (either reducing or quitting smoking) increased from $18 \%$ in 1995 to $26 \%$ in 1996) (Table 1). The percentage who reported quitting remained the same ( $5 \%$ in 1995 versus $6 \%$ in 1996); however, the percentage who reported reducing their smoking during the GASO increased significantly, from 13\% in 1995 to $20 \%$ in 1996. In 1996, reports of smoking behavior were examined at the time of the interview (1-5 days following the GASO): $6 \%$ of respondents reported quitting smoking, while $15 \%$ reduced their smoking.

Smoking-cessation activity involving the use of nicotine medications was estimated using retail sales of such products as reported by InFact. During the 4-week GASO promotional period, sales of nicotine medications increased by $11 \%$ (136,000 units), compared with sales during the baseline period. The proportion of units purchased by new users or by repeat purchasers cannot be determined precisely; however, the smallest package of OTC nicotine medication provides approximately 7 days of therapy; therefore, in this analysis, only the increase in sales during the week ending November 23 was assumed to be due to new purchasers and thus new quit attempts." Compared with weekly average sales during the entire 4 -week baseline period ( 306,400 units), sales during the week ending November 23 increased $30 \%$ ( 92,600 units), representing a total of 399,000 units. Thus, the enhanced promotional activities and the GASO promotion were associated with an estimated 92,600 attempts at quitting smoking using nicotine medications.
Reported by: SL Burton, KE Kemper, TA Baxter, SmithKline Beecham Consumer Healthcare; S Shiffman, Smoking Research Group, Dept of Psychology, Univ of Pittsburgh, Pittsburgh, Pennsylvania. J Gitchell, Pinney Associates, Bethesda, Maryland. C Currence, American Cancer Society, Atlanta, Georgia. Epidemiology Br, Office on Smoking and Health, National Center for Chronic Disease Prevention and Health Promotion, CDC.
Editorial Note: Based on nationally representative data for 1965-1994, the prevalence of cigarette smoking in the United States appears to have reached a plateau of approximately $25 \%(2,3)$. Reducing the initiation of smoking among youth is a priority reflected in the Food and Drug Administration's final tobacco rule, as well as in ongoing public education and awareness efforts such as the GASO. In addition, encouraging cessation is a priority; reducing adult smoking produces substantial
©No evidence suggests the promotion increased repeat purchases.

## GASO Promotion and OTC Nicotine Medications - Continued

short-term and long-term benefits in health improvements and cost savings (4). Since 1977, ACS has sponsored the annual GASO to encourage smokers to stop smoking for at least 24 hours. Evaluation of mass media campaigns and previous GASO efforts suggests that public promotions can increase smoking-cessation activity (5,6).

The findings in this report suggest that the GASO promotional campaign and OTC availability of nicotine medications encouraged smoking-cessation activity. These findings illustrate the substantial impact of an intensive event-related campaign in promoting smoking-cessation activity. In comparison, data from another source on the use of nicotine medications in 1995 indicated only a $2 \%$ monthly increase in nicotine medication prescriptions for November over the annual average; however, there was no promotional campaign nor OTC availability of the products (7). OTC availability of the nicotine patch and nicotine gum appears to remove a possible barrier to their use (i.e., obtaining a prescription) and allows more direct promotion of these products and smoking cessation to the general public.

A recent analysis conducted in a setting that simulated OTC availability of three currently available OTC nicotine medications found a continuous (biochemically validated) quit rate of $8 \%$ at 12 months using data pooled across studies (8). Using the single-week comparison as the most valid indicator of initial quitting attempts (rather than repurchase) and assuming that any product purchased was used for a quit attempt, the increase in nicotine medication use attributable to the 1996 GASO promotion produced an estimated 7400 additional former smokers.

The findings in this report are subject to at least three limitations. First, because no record was maintained of nonrespondents for the Lieberman surveys, response rates could not be calculated. As a result, the level of response bias cannot be determined. Second, the sampling methods of the 1995 and 1996 surveys were different; however, data from both surveys were weighted to produce nationally representative data and, therefore, were considered comparable. Third, the estimate of the impact of the promotional campaign on smoking cessation may not be precise because all purchasers of nicotine medications were assumed to be the user of the product and because retail sales data comprise both new and repeat purchases.

The findings in this report suggest that promoting smoking cessation can increase quit attempts. Smokers interested in quitting smoking should be strongly encouraged to do so and should optimize their chances for quitting by using effective treatments as outlined by the Agency for Health Care Policy and Research (9). Marketing and promotion efforts designed to promote attempts to quit, along with OTC availability of nicotine medications, are a useful part of a national strategy to decrease the prevalence of smoking.

Reprinted below is the first published report (published December 8, 1973) of a large-scale systematic study of community exposure to emissions from a lead smelter.

## EPIDEMIOLOGIC NOTES AND REPORTS

## HUMAN LEAD ABSORPTION - Texas

In December 1971, the City-County Health Department in El Paso, Texas, discovered that an ore smelter in El Paso was discharging large quantities of lead and other metallic wastes into the air. Between 1969 and 1971, this smelter had released 1,116 tons of lead, 560 tons of zinc, 12 tons of cadmium, and 1.2 tons of arsenic into the atmosphere through its stacks (Table 1).

Twenty-four hour air samples to determine the amounts of lead and other heavy metals suspended in the atmosphere were collected throughout 1971 and again between July 1972 and June 1973 by the local health department. Both series of tests showed that mean concentrations of metallic wastes in the air were highest immediately downwind of the smelter and that levels decreased logarithmically with distance from the smelter. The annual mean lead level immediately downwind of the smelter in 1971 was $92 \mu \mathrm{G} / \mathrm{m}^{3}$ and in 1972-73 was $43 \mu \mathrm{G} / \mathrm{m}^{3}$; the U.S. Environmental Protection Agency's proposed safe upper limit for airborne lead content is $2.0 \mu \mathrm{G} / \mathrm{m}^{3}$ of air (1). No metallic emissions were found near any of 15 other industrial establishments studied in El Paso.

## Human Lead Absorption - Continued

Similarly, soil samples taken by the health department at selected sites within the urban area between June and December 1972 showed the highest concentrations of lead and other metals to be in surface soil from within 0.2 miles of the smelter (Figure 1). Samples of drinking water, milk, and food obtained from homes in El Paso between January and March 1972 by the health department were uniformly free of lead.

Preliminary testing programs to evaluate the effect of the environmental contamination on human blood lead levels were conducted in El Paso between January and March 1972 by the local health department, the smelting company, and CDC. These initial studies showed that $43 \%$ of persons in all age groups and $62 \%$ of children through age 10 years living within 1 mile of the smelter had blood lead levels $\geq 40 \mu \mathrm{G} \%$, a level considered to be evidence of undue lead absorption (2). There was a lower prevalence among persons living at greater distances from the smelter. No cases of overt lead poisoning were noted.

In August 1972, a random survey of the entire population living within 4.1 miles of the smelter in south and west El Paso was conducted by the health department and CDC. The area was divided along census tract lines into 3 strata, roughly concentric about the smelter and each with a radius of 1.0-1.5 miles. In the small, innermost stratum, all households were visited; in the 2 outer strata, approximately $2 \%$ of households were selected. Of 833 occupied households included in the survey, 672 (80.6\%) were reached for the interview. A venous blood sample for lead analysis by atomic

Figure 1
LEAD SURFACE SOIL LEVELS EL PASO, TEXAS, AND DONA ANA COUNTY, NEW MEXICO — 1972

## Human Lead Absorption - Continued

absorption spectrophotometry (AAS) was obtained from all persons up to age 20 years and from every other person above that age; samples of paint, soil, household dust, and pottery were also collected in each home for lead analysis by AAS. In all age groups, the percentage of blood levels $\geq 40 \mu \mathrm{G} \%$ was found to be highest in those persons living nearest the smelter (Figure 2), and the prevalence was highest in the youngest individuals; migration rates among these persons were low. In area I, 5 ( $8.5 \%$ ) of 59 persons 1-19 years of age with blood lead levels $\geq 40 \mu \mathrm{G} \%$ had moved into the area in the 2 years preceding the survey. In areas II and III, the migration rate for persons 1-19 years of age with blood levels $\geq 40 \mu \mathrm{G} \%$ was $8.2 \%$ ( 4 of 49); 1 person in this group had moved from areal.

A total of 1,971 paint samples were collected for lead analysis. In area I, 9 (39.1\%) of 23 children 1-4 years had exposure to at least 1 paint sample with a lead content of $1.0 \%$ or more; the comparable figures for areas II and III were 11 ( $33.3 \%$ ) of 33 and 17 ( $34.0 \%$ ) of 50 children, respectively. These three rates were virtually identical ( $p>0.9$ by Chi-square).

Analysis of over 4,000 soil and household dust samples indicated that the mean content of lead in these specimens was significantly higher in area I than in areas II and III. Furthermore, persons 1-19 years with blood lead levels $\geq 40 \mu \mathrm{G} \%$ were found to have been exposed to soil and dust samples with significantly higher ( $p<0.001$ ) mean lead contents ( $3,264 \mathrm{ppm}$ for soil, $3,522 \mathrm{ppm}$ for dust) than persons with blood lead levels below $40 \mu \mathrm{G} \%$ (means: 1,032 ppm and 1,279 ppm).

Pottery vessels were used for food storage or preparation in 37 homes visited. After $1 \%$ hydrochloric acid incubation for 6 hours, 2 of 6 vessels from sector I, 6 of 19 from sector II, and 4 of 12 from sector III had a lead content $\geq 100 \mathrm{G}$ per ml in the eluate.
(Reported by Bernard F. Rosenblum, M.D., M.P.H., Director, El Paso City-County Health Department; James M. Shoults, Acting Environmental Engineer, El Paso City-County Health Department; J. Julian Chisolm, Jr,. M.D., Chief of Pediatrics, Baltimore City Hospitals; Community and Environmental Management Activities, Bureau of State Services, CDC; the Field Services Branch, Bureau of Epidemiology, the Toxicology Section, Clinical Chemistry, Hematology, and Pathology Branch, Bureau of Laboratories, CDC; and a team of EIS Officers.)
Editorial Note: It may be estimated from this prevalence survey, using 1970 U.S. Census data, that at least 2,700 persons 1-19 years of age in El Paso had blood lead levels $\geq 40 \mu \mathrm{G} \%$ at the time of the survey (Table 2). These results indicate that the problem of undue lead absorption affects persons across all of south and west El Paso to a distance of at least 4 miles from the smelter. Lead emitted by the smelter and deposited in soil and dust would appear to be the major source of the lead absorbed by humans; the accumulation in the soil and dust of emitted lead is facilitated by several features of the local environment, particularly the aridity, the sheltering effect of the high mountains, and the frequent thermal inversions. Ingestion of lead-based paint may account for a small fraction of cases of undue absorption (at most $1 / 3$ ) in the youngest children. Careful neurologic and psychologic studies of persons in El Paso with blood lead levels $\geq 40 \mu \mathrm{G} \%$ have been conducted and are being compared with results of similar studies in a matched group with lower lead levels. This story will make it possible to ascertain objectively whether any persons are suffering subtle but possibly permanent neurologic or psychologic sequelae from prolonged lead absorption.

Control measures undertaken to date include partial reduction of smelter emission and relocation to more distant public housing of approximately 500 persons who had lived closely adjacent to the smelter property.

Editorial Note-1997: When a team of Epidemic Intelligence Service officers from CDC, led by Dr. Philip Landrigan, joined the local health department in El Paso, Texas, in March 1971 to investigate lead exposure associated with an ore smelter, the scientific understanding of pediatric lead toxicity was about to enter a period of rapid progress. Many studies have since documented the public health threat posed by poorly controlled lead emissions from lead smelters around the world (1). The range of lead

exposure produced in populations living near lead smelters has, in turn, facilitated studies of the mechanisms and health consequences of pediatric lead exposure.

A major objective of the El Paso investigation was to determine whether high blood lead levels (BLLs) in children were associated with smelter emissions or were explained by other lead sources also found in the community. A high level of lead emissions in a residential area was not then assumed to be a public health threat, as it is today. A 1972 National Academy of Sciences report on lead, while motivated by growing concern about widespread dispersal of lead in the environment, stated in its preface: "lead attributable to emission and dispersion into the general ambient environment has no known harmful effects" (2). In El Paso, the inverse gradient in air (3), dust, and soil contamination as one moved away from the smelter, and the parallel blood lead gradient (also found in a complementary investigation of lead exposure in Juarez, Mexico [4 ]) supported the argument that soil and dust are important vehicles of exposure. This finding foreshadowed subsequent research demonstrating the pathway from lead in soil and dust to lead contamination of hands to lead in blood, presumably from normal hand-to-mouth behavior and ingestion of contaminated soil and dust (5-7).

In 1975 and 1976, CDC investigators, led by Dr. Edward Baker, documented the potential for exposure to leaded dust among children of workers at a secondary lead smelter in Tennessee (8). Their findings and those of other investigations of "takehome" lead exposure that followed brought about provisions in the 1978 Occupational Safety and Health Administration (OSHA) standard for occupational lead exposure requiring hygienic measures in general industry to prevent lead workers from carrying lead dust home on their skin, shoes, and clothing (9).

In the 1960s and 1970s, children living near smelters or in the households of smelter workers were only a small part of a widespread national problem of "undue lead absorption" (10). In urban areas, deteriorated lead paint in older housing made the problem especially acute. In the same year as the EI Paso survey, a door-to-door survey of inner-city children in Rochester, New York, found a mean BLL of $44 \mu \mathrm{~g} / \mathrm{dL}$ (5), which was close to that measured near the EI Paso smelter.

Since the early 1970s, it also has become more clear that lead is a multimedia contaminant and that demonstrating the importance of a given source does not rule out the contribution of other sources. For example, data from the Second National Health

## Human Lead Absorption - Continued

and Nutrition Examination Survey (NHANES II) conducted from 1976 through 1980 indicated that the mean BLL among children aged <6 years residing in rural areas was $14 \mu \mathrm{~g} / \mathrm{dL}$ (average levels were $3-6 \mu \mathrm{~g} / \mathrm{dL}$ higher among children living in more urbanized areas) (11). During the same period, widespread population exposure to lead emissions was reflected in average BLLs that declined in close parallel to the decreasing consumption of leaded gasoline (12). Thus, children living near the El Paso smelter, children in the homes of lead workers, and children in downtown Rochester probably shared with children across the country a contribution to their BLLs from lead in gasoline. Local sources, added to the higher background exposure prevalent at the time, resulted in BLL distributions that are extremely high by today's standards.

Perhaps the most telling indication of how the scientific view of lead exposure has changed since 1971 is that, in 1971 "undue lead absorption" referred only to BLLs $\geq 40 \mu \mathrm{~g} / \mathrm{dL}$. Numerous subsequent studies documented that BLLs much lower than $40 \mu \mathrm{~g} / \mathrm{dL}$, then considered acceptable, adversely impact the health of children without causing overt symptoms. For example, investigators from CDC's Bureau of Epidemiology, again led by Dr. Landrigan, found an inverse relation between BLLs and nerve conduction velocities among children exposed to emissions from a smelter near Kellogg, Idaho (13). As the decade closed, Dr. Herbert Needleman's landmark study was published, demonstrating lower cognitive test scores and higher teachers' ratings of behavioral problems among children with higher tooth lead levels but no history of clinically overt lead poisoning (14).

Epidemiologic studies identified subclinical effects of lead by comparing the health of children with different levels of lead exposure. For most U.S. populations studied in the 1970s, the least exposed children had BLLs well above the average in the U.S. population today. Thus, health effects at lower levels could not be detected. As population BLLs decreased through the 1980s, careful prospective studies found subtle effects of lead on learning and behavior at BLLs well below those of the least exposed children in El Paso (15).

In addition to contributing to scientific knowledge about lead exposure and its effects on health, findings from the El Paso survey and others precipitated measures to reduce emissions at lead smelters. In 1977, a follow-up investigation by CDC and the El Paso Health Department found that BLLs among children living nearest the smelter had decreased by approximately $50 \%$ ( 16 ). More importantly, the EI Paso survey was a prelude to a large body of continuously refined epidemiologic investigations that provided the impetus for actions to dramatically reduce population lead exposure from lead in gasoline, soldered food cans, drinking water conduits, and other sources in the United States. As a result, mean BLLs among children have declined nationally by $>80 \%$ overall and by similar amounts in population subgroups defined by age, race, ethnicity, income levels, and urbanization (17,18). More recently, international agreements to reduce the use of leaded gasoline may bring about significant reductions in worldwide lead exposure. Ironically, the unfortunate epidemics of lead toxicity near smelters in El Paso and elsewhere ultimately enabled more rapid progress in understanding and controlling lead exposure than might otherwise have been possible.
1997 Editorial Note by Thomas Matte, MD, MPH, Medical Epidemiologist, Henry Falk, MD, Director, Division of Environmental Hazards and Health Effects, National Center for Environmental Health, CDC.

## Asthma Mortality — Illinois, 1979-1994

Asthma is a chronic inflammatory disorder of airways characterized by variable airflow obstruction with airway hyperresponsiveness. In the United States, the mortality rate associated with asthma has increased steadily since 1979 (1,2). Uneven distributions of deaths attributable to asthma have been observed among different racial/ ethnic groups ( 3,4 ). To examine the distribution of asthma deaths in Illinois, trends in asthma death rates were analyzed for 1979-1994 for Illinois residents. This report presents the findings of this analysis, which indicated that, compared with asthma death rates in the United States for 1982-1991, rates in Illinois were higher and the asthma mortality ratio for blacks to whites was higher.

## Asthma Mortality - Continued

Asthma deaths were abstracted from vital records listing asthma as the underlying cause of death (International Classification of Diseases, Ninth Revision, codes 493.0493.9). Intercensal population estimates for Illinois were obtained from the U.S. Bureau of the Census. Because of the high accuracy of diagnosing asthma in persons aged $<35$ years ( $>95 \%$ ) ( 5 ), this analysis presents age-adjusted death rates for persons aged 5-34 years. Calculations of race-specific rates were limited to blacks and whites because numbers for other races were too small to enable estimation of stable rates.

During 1979-1994, the annual age-adjusted asthma death rate for persons aged $5-34$ years in Illinois increased by $341 \%$, from 3 per million to 15 per million. From 1982 to 1991, the increase was $57 \%$, higher than the national average of $42 \%$ for the same period (1). Except in 1986, the annual death rate was consistently higher in Illinois than in the United States by an average of $56 \%$. Annual rates and increases were similar for males and females during 1979-1994 in Illinois.

The death rates for asthma were higher among blacks than whites. The asthma death rate for whites in Illinois was indistinguishable from that for whites nationally; however, the death rate for blacks in Illinois was twice as high as the national rate for blacks for most years from 1982 through 1991 (Figure 1). This resulted in a greater black-to-white asthma mortality ratio in Illinois (9) than nationally (<5). This ratio increased to 10 in 1994 in Illinois.
Reported by: HL Howe, PhD, L Landrum, MS, JR Lumpkin, MD, Illinois Dept of Public Health. Div of Applied Public Health Training (proposed), Epidemiology Program Office, CDC.

## Asthma Mortality — Continued

Editorial Note: An estimated 14 million persons in the United States are affected by asthma (6), and each year, 4000-5500 deaths are caused by asthma. In addition, morbidity and mortality from asthma have continuously increased and have had a disproportional impact on some population subgroups (7). Although acute episodes of asthma can be fatal, most deaths from asthma are preventable with appropriate medical management (7).

Changes in both prevalence and severity of asthma could affect mortality. The prevalence of asthma has increased in the United States (8) with increased recognition and diagnosis of asthma by physicians; increased exposure to environmental allergens and irritants; and increased exposure of children to maternal smoking, household crowding, and poverty ( $1,2,8$ ). Factors associated with the increased risk for death from asthma include excessive exposure to allergens and air pollution; underestimation of the severity of asthma; psychosocial instability; overuse of inhaled, short-acting $\beta$-agonists; underuse of corticosteroids; substance abuse; and inadequate access to appropriate health care (1-3,7).

The higher overall rate of asthma mortality and the wider gap between the rates for blacks and whites in Illinois than in the United States primarily were because of the high death rate for blacks rather than a lower death rate for whites. Additional study is needed to determine reasons for the race-specific differences in the rates. Previous studies comparing mortality from asthma between blacks and whites indicate that asthma mortality, regardless of race, is inversely correlated with income ( $4,9,10$ ). This disparity in asthma mortality between blacks and whites is associated with the generally lower socioeconomic status (SES) for blacks and possibly attributable to greater exposure to allergens and pollutants and poor access to and use of appropriate health care among persons of lower SES (7).

State and territorial public health agencies have a critical role in the surveillance and prevention of asthma morbidity and mortality. Most states do not have asthma surveillance and prevention programs (6). CDC encourages states to actively use existing asthma-related data to assess the local burden of asthma and to use that information to target asthma-control and asthma-prevention programs to at-risk populations ( 6,8 ).

*Mortality data in this table are voluntarily reported from 122 cities in the United States, most of which have populations of 100,000 or more. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.
${ }^{\dagger}$ Preumonia and influenza.
${ }^{\S}$ Because of changes in reporting methods in this Pennsylvania city, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks.
TTotal includes unknown ages.

The Morbidity and Mortality Weekly Report (MMWR) Series is prepared by the Centers for Disease Control and Prevention (CDC) and is available free of charge in electronic format and on a paid subscription basis for paper copy. To receive an electronic copy on Friday of each week, send an e-mail message to listserv@listserv.cdc.gov. The body content should read SUBscribe mmwr-toc. Electronic copy also is available from CDC's World-Wide Web server at http:/ /www.cdc.gov/ or from CDC's file transfer protocol server at ftp.cdc.gov. To subscribe for paper copy, contact Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402; telephone (202) 512-1800.

Data in the weekly MMWR are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the following Friday. Address inquiries about the MMWR Series, including material to be considered for publication, to: Editor, MMWR Series, Mailstop C-08, CDC, 1600 Clifton Rd., N.E., Atlanta, GA 30333; telephone (888) 232-3228.

All material in the $M M W R$ Series is in the public domain and may be used and reprinted without permission; citation as to source, however, is appreciated.

Deputy Director, Centers for Disease Control and Prevention Claire V. Broome, M.D.
Director, Epidemiology Program Office Stephen B. Thacker, M.D., M.Sc.
Editor, MMWR Series
Richard A. Goodman, M.D., M.P.H.

[^0]:    *Single copies of this report will be available until September 19, 1998, from the CDC National AIDS Clearinghouse, P.O. Box 6003, Rockville, MD 20849-6003; telephone (800) 458-5231 or (301) 217-0023.
    ${ }^{\dagger}$ Categories included persons aged 20-64 years of white, black, or Hispanic race/ethnicity but excluded persons infected through receipt of contaminated blood/blood products and persons with other or no risks reported.
    ${ }^{5}$ Conditions in HIV-infected persons that were added to the AIDS case definition in 1993 included laboratory measures of severe immunosuppression (i.e., CD4+ T-lymphocyte count $<200$ cells $/ \mu \mathrm{L}$ or percentage of total lymphocytes $<14$ ) and three clinical conditions: pulmonary tuberculosis, recurrent pneumonia, and invasive cervical cancer.

[^1]:    T Northeast=Connecticut, Maine, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, and Vermont; Midwest=Illinois, Indiana, lowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, Ohio, South Dakota, and Wisconsin; South=Alabama, Arkansas, Delaware, District of Columbia, Florida, Georgia, Kentucky, Louisiana, Maryland, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, Virginia, and West Virginia; and West=Alaska, Arizona, California, Colorado, Hawaii, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington, and Wyoming.

[^2]:    *Points represent quarterly incidence; lines represent "smoothed" incidence. Estimates are not adjusted for incomplete reporting of AIDS cases.

[^3]:    * Standard promotion of the GASO is organized and promoted by ACS volunteers and staff and consists of local activities in malls, businesses, restaurants, hospitals, colleges, and military bases.

[^4]:    ${ }^{\dagger}$ SmithKline Beecham Consumer Healthcare; Smoking Research Group, University of Pittsburgh; Pinney Associates; ACS; and CDC.
    § Use of trade names and commercial sources is for identification only and does not imply endorsement by the Public Health Service or the U.S. Department of Health and Human Services.

[^5]:    * In 1995, a survey of 5504 adults aged $\geq 21$ years was conducted, and in 1996 , a survey of 983 adults aged $\geq 21$ years was conducted. Data for each year were weighted to produce national estmates for the respective year.
    ${ }^{\dagger}$ Confidence interval
    ${ }^{\S}$ Degrees of freedom.
    ${ }^{\text {IE Either attempts to reduce or quit smoking. }}$

[^6]:    * Per 1 million persons, age standardized to the 1980 U.S. population.
    ${ }^{\dagger}$ Data are presented only for blacks and whites because numbers for other races were too small to calculate stable estimates.
    ${ }^{\S}$ Reference 1.
