# Barriers to Dietary Control Among Pregnant Women with Phenylketonuria — United States, 1998–2000

Newborns in the United States are screened for phenylketonuria (PKU), a metabolic disorder that when left untreated is characterized by elevated blood phenylalanine (phe) levels and severe mental retardation (MR). An estimated 3,000-4,000 U.S.-born women of reproductive age with PKU have not gotten severe MR because as newborns their diets were severely restricted in the intake of protein-containing foods and were supplemented with medical foods (e.g., amino acidmodified formula and modified low-protein foods) (1-4). When women with PKU do not adhere to their diet before and during pregnancy, infants born to them have a 93% risk for MR and a 72% risk for microcephaly (5-6). These risks result from the toxic effects of high maternal blood phe levels during pregnancy, not because the infant has PKU (5-6). The restricted diet, which should be maintained for life, often is discontinued during adolescence (5-10). This report describes the pregnancies of three women with PKU and underscores the importance of overcoming the barriers to maintaining the recommended dietary control of blood phe levels before and during pregnancy. For maternal PKUassociated MR to be prevented, studies are needed to determine effective approaches to overcoming barriers to dietary control.

During the fall of 2000, CDC conducted an interview-based study of women with PKU who were aged ≥18 years and pregnant during 1998–2000 (index pregnancy), regardless of dietary management or pregnancy outcome. Women were recruited from three metabolic clinics that provided services funded by state and private sources and were interviewed using a structured questionnaire that was completed in person or by telephone. Medical records were requested to document timing of diet initiation, control of blood phe levels

(defined as 2–6 mg/dL), and pregnancy outcome. The study protocol was approved by CDC's Institutional Review Board, and informed consent was obtained from each respondent.

A total of 30 women met the interview criteria; two could not be contacted. Of the 28 remaining women, 24 were interviewed (17 in person and seven by telephone). The median age was 28 years (range: 22–38 years); 75% were married, 96% were white, and 50% had a high school education or less. A total of 51 pregnancies had occurred among 24 women. Among the 24 index pregnancies, 18 (75%) resulted in live-born infants; 11 (46%) pregnancies were intended.

The use of formula-based medical foods before conception was reported more often among the 11 women who were trying to conceive than among those who were not (risk ratio=3.5; 95% confidence interval=1.6–10.2). Use of modified, low-protein medical foods to diversify the diet was reported only among women trying to conceive. No difference was reported in avoiding high-protein foods between women who were and who were not trying to conceive. One woman remained on the restricted diet throughout adulthood; 23 women had been off the diet for 6–24 years (average: 16 years). At the time of the interview, 17 (71%) women were not using medical foods (65% because of the unpleasant taste). A total of 22 women had resumed the diet before or during their index pregnancy, eight (33%) women had contacted the metabolic clinic

#### Notifiable Disease Morbidity and 122 Cities Mortality Data

Carol M. Knowles Deborah A. Adams Felicia J. Connor Patsy A. Hall Mechele A. Hester Pearl C. Sharp before conception, and 11 (46%) had contacted the metabolic clinic after conception but by week 10 of gestation. Of the 22 medical records available, 12 (55%) records indicated controlled blood phe levels before 10 weeks of gestation.

All of the women expressed confidence in their metabolic clinic staff's knowledge of a phe-restricted diet and maternal PKU; eight (33%) perceived that their obstetricians were knowledgeable about maternal PKU. Approximately equal numbers of women used public assistance and private insurance to cover the costs associated with clinic visits (Table 1). Costs of medical foods were more often covered by public assistance than by private insurance (Table 1). Among the 13 women who used public assistance, nine (69%) reported that proof of pregnancy was required to receive services. When the data were stratified by state of residence, women in state C had the lowest rate of live births resulting from their pregnancies, lowest use of formula before pregnancy, fewest women achieving metabolic control before 10 weeks' gestation, and longest commutes to a metabolic clinic (Table 2). These differences were not significant by Fisher exact test.

#### **Case Reports**

Case 1. A woman aged 21 years discontinued formula use in early adolescence and lost contact with the metabolic clinic. Although she was aware of the need to follow the diet during pregnancy, she did not seek care when she became pregnant. PKU was listed in her prenatal medical records; however, her obstetrician did not refer her to a metabolic clinic or a maternal-fetal specialist and did not recommend dietary intervention or regular monitoring of her phe levels. Her pregnancy resulted in an infant with microcephaly and developmental delay.

Case 2. A woman aged 21 years discontinued formula use in early adulthood because of limited financial resources. She reported willingness to adhere to the diet during pregnancy, but lack of transportation, financial constraints, and inability to take time off from work prohibited her from accessing care at the nearest metabolic clinic, which was 3 hours away. She met with local health department staff several months into

<sup>\*</sup> Percentages reflect denominator of medical records received from each state (A=6, B=7, and C=9).

the pregnancy to acquire formula. PKU was included in her prenatal medical records, and she was referred to a maternal-fetal specialist; however, her blood phe levels were not monitored, and she was not referred to a metabolic clinic. Her pregnancy resulted in an infant with microcephaly.

Case 3. A woman aged 27 years remained on the PKU diet throughout adulthood, planned her pregnancy, and had her blood phe levels in control before conception. Her private insurance covered part of her diet-related medical treatment costs. She estimated that out-of-pocket expenses for the portion of the metabolic clinic visits not paid by insurance were \$2,300 during her pregnancy. Her insurer denied coverage for formula, low-protein foods, and blood tests to examine her full amino acid profile. The metabolic clinic provided the formula without reimbursement from the insurance company. Her pregnancy resulted in a healthy infant.

Editorial Note: This report highlights some barriers that prevent metabolic control of blood phe levels before pregnancy among women with PKU. Two thirds of the women in this study had not followed the diet before becoming pregnant. This demonstrates limited adherence to prepregnancy medical recommendations among these women. Women also reported limited confidence in obstetricians' knowledge of maternal PKU management and inconsistencies between medical recommendations and health insurance coverage. Following the lifelong diet also was complicated by the unpleasant taste of medical foods.

The findings in this report are subject to at least three limitations. First, the sample size was small and consisted mostly of women who received dietary management from metabolic clinics during pregnancy. These women might have had access to more resources or been more willing to adhere to medical recommendations than women who had not received such care. Second, at the time of the interviews, most of the women were not following their diets; persons with PKU who are not on the diet might have difficulties with concentration and memory that could compromise the accuracy of their responses. Third, the three clinics participating in this study do not represent all U.S. metabolic clinics.

To improve pregnancy outcomes for women with PKU, health-care providers should be trained to advise women to plan their pregnancies, return to diet, and stay on the diet for life. Additional evaluation is needed to ascertain the knowledge needed by obstetricians to guide women with PKU; third-party payers could identify disparities in financial assistance available to pregnant women with PKU and determine the most cost-effective approaches. Additional examination of these barriers would allow public health programs to establish effective methods to reduce obstacles and improve pregnancy outcomes for women with PKU.

#### Measles — United States, 2000

In 2000, a provisional total of 86 confirmed measles cases were reported to CDC by state and local health departments, representing a record low and a 14% decrease from the 100 cases reported in each of the previous 2 years (1,2). This report describes the epidemiology of measles in the United States during 2000 and documents the continued absence of endemic measles and the continued risk for internationally imported measles cases that might result in indigenous transmission.

Following state laws and regulations, health-care providers, laboratories, and other health-care personnel report confirmed measles cases to state public health departments; this information is forwarded to CDC (3). Data on vaccination status, age, complications, setting of transmission, and serologic confirmation of cases also are collected.

Of the 86 reported measles cases, 26 (30%) were internationally imported\*. Of the 60 indigenous cases, 18 were import-linked, nine were imported virus, and 33 were of unknown source. Importation-associated cases (i.e., imported, import-linked, and imported virus cases) accounted for 62% of all reported cases.

The proportion of cases classified as "internationally imported" cases has been relatively stable since 1998 (Figure 1). Of the 26 imported cases, 14 occurred in United States residents who had traveled abroad and 12 in international visitors. Measles was imported from 10 countries. The largest numbers of imported cases reported were from Japan (seven cases) and Korea and Ethiopia (four each). The states reporting the most imported measles cases were New York (eight cases), California (six), and Hawaii and Vermont (three each). Four counties had more than one imported case in 2000.

On average, imported cases resulted in <1 import-linked case (range: 0-5). Measles virus was isolated from eight chains of transmission linked to an imported measles case (including three chains of one case). In each chain, the viral genotype sequenced was consistent with the genotype of virus known to be circulating in the source country of the imported case. Virologic evidence of importation was found in five chains of transmission (nine cases) that were not linked epidemiologically to imported cases. Genotype D5 was cultured from two isolated cases and genotypes G2, H1, and H2 were each isolated from one chain of transmission. These genotypes are known to circulate in Japan, China, and Vietnam, respectively. The lack of any consistently repeating genotype indicates that there is no endemic genotype. Therefore, all indigenous cases with genotype information and no epidemiologic link to an imported case were classified as imported virus cases.

During 2000, a total of 20 states reported confirmed measles cases. Three states accounted for 57% of cases: New York (23 [13 from New York City]), California (19), and Nevada (seven). The remaining 17 states each reported from one to three measles cases. Of the 3,140 counties in the United States, 41 (1%) reported a confirmed measles case; seven counties (<1%) reported more than three cases.

In 2000, 68 (79%) of the 86 reported cases occurred during weeks 1–26, and 18 (21%) occurred during weeks 27–52. The median number of cases per week was one (range: 0–9). During 18 weeks, no cases were reported. During 17 additional weeks, all reported cases were import-associated. During five periods of 4 weeks, all reported cases were import-associated (Figure 2).

Ten cases (12% of total cases) were in infants aged <12 months, 27 (31%) in children aged 1–4 years, 17 (20%) in persons aged 5–19 years, 20 (23%) in persons aged 20–34 years, and 12 (14%) in persons aged  $\geq$ 35 years. Of the 86 patients, 23 (27%) had a documented history of measles vaccination; 40 (46%) had not been vaccinated, nine of these were aged <12 months; and 23 (27%) patients had unknown

<sup>\*</sup>Imported=cases among persons who were infected outside the United States; Indigenous=cases in persons infected in the United States. Indigenous cases are subclassified into three groups: import-linked=cases epidemiologically linked to an imported case (virologic evidence of importation is not required for this classification); imported virus=cases that cannot be linked epidemiologically to an imported case but for which imported virus has been isolated from the case or from an epidemiologically linked case; and unknown source=all other cases acquired in the United States for which no epidemiologic link or virologic evidence has been found to indicate importation.

FIGURE 1. Number and percentage of internationally imported measles cases — United States, 1991–2000

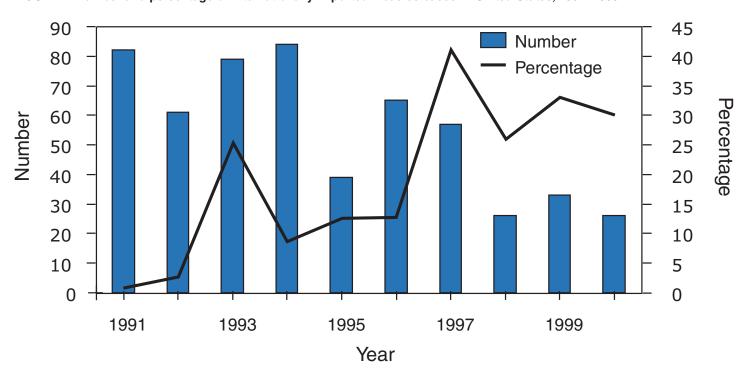

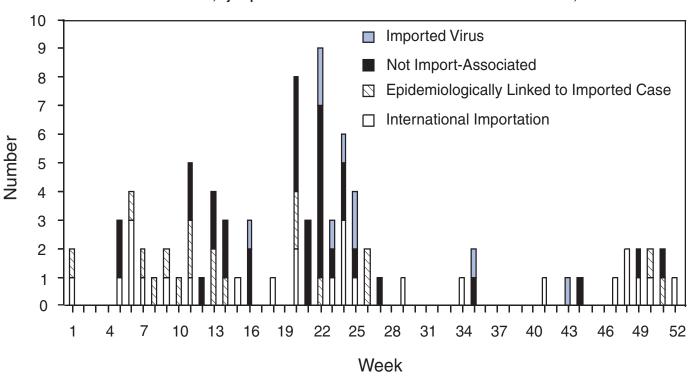

FIGURE 2. Number of measles cases, by importation status and week of rash onset — United States, 2000

vaccination status. Among 48 cases in persons for whom vaccine was recommended and vaccination status was known, 24 (50%) were unvaccinated.

Of 71 cases in U.S. residents (57 indigenous and 14 imported), 54 (77%) occurred in vaccine-eligible persons. Of these residents, 20 (37%) were known to be vaccinated, 20 (37%) were not vaccinated, and 14 (26%) had unknown vaccination status.

In 2000, 10 measles outbreaks (i.e., three or more confirmed cases) occurred in nine states accounting for 48 (56%) of the 86 cases. An epidemiologic link to an imported case was documented in five of the 10 outbreaks.

The largest outbreaks occurred in New York: one in Oswego/Onondaga counties involving nine persons and a second in Kings County involving eight persons. The Oswego/Onondaga outbreak occurred in a high school; the source of infection was unknown. Of the six high school students eligible for vaccination, five had been vaccinated. Each of these students had received a single dose of measles vaccine, which was in compliance with state requirements at that time. The outbreak in Kings County occurred in a religious community in Brooklyn following an imported case from the United Kingdom. Two cases were in infants aged <12 months. Among the six patients who were vaccine eligible, three were unvaccinated.

One outbreak in 2000 illustrates the difficulty in linking indigenous cases to their imported source. A U.S. resident and Olympic athlete aged 24 years developed prodromal measles symptoms while competing in an athletic event in Utah. The athlete had no known exposure to measles; however, 2 weeks before arriving in Utah, she had participated in an athletic competition in Japan. Following the competition in Utah, the athlete flew to Italy and subsequently developed a rash consistent with measles. The team physician notified CDC of the case from Italy. On return to the United States, the athlete tested IgM positive for measles. Three confirmed measles cases were linked epidemiologically to the athletic event in Utah. No viral strain was obtained from any of the cases.

**Reported by:** M Papania, MD, S Redd, W Bellini, PhD, Div of Viral and Rickettsial Diseases, National Center for Infectious Diseases; Epidemiology and Surveillance Div, National Immunization Program; and B Lee, MD, EIS Officer, CDC.

**Editorial Note:** Measles is still endemic in many countries and results in approximately 800,000 deaths per year (4). However, the reported incidence of measles in the United States has been <1 case per million for the past 4 years (1). The high percentage of cases resulting from importations and

very limited indigenous spread from these imported cases also has continued over the same period. The consistently small number of unknown source cases suggests that measles is no longer endemic in the United States. However, unknown source cases continue to occur sporadically. Many of these cases, especially isolated cases, might be misclassifications resulting from false-positive laboratory tests. However, even among true measles cases, it is impossible to identify the imported case in every chain of transmission.

The outbreak in Utah demonstrates the difficulty in linking every case to an imported source. CDC was informed of the case only because it occurred in an Olympic athlete. The case was not reported as a U.S. case because rash onset and diagnosis had occurred in Italy. If the team physician had not called from Italy to report this case, the three associated cases in Utah would have been classified as unknown source cases. Because most visits to the United States are of a relatively short duration, many persons shedding measles virus might leave the country before the rash begins and before measles is diagnosed. Many other international visitors who develop measles in the United States might choose to return home before they seek care because they are unfamiliar with the U.S. health-care system or lack valid health insurance in the United States. In both situations, the imported case would not be detected except under special circumstances.

Difficulty in epidemiologically linking every case to an imported source highlights the crucial role of virologic surveillance in monitoring the absence of endemic measles. Collection of viral specimens is an important part of any measles case investigation. Worldwide, during large outbreaks (5,6) or in areas where disease is endemic (7,8), one measles genotype is usually found. Since 1992 in the United States, no genotypes have been found consistently, and when genotypic data are available, all isolates from imported cases have the genotype found in the country of origin (5,9).

Imported measles cases consistently test the level of population immunity to measles in the United States. The average of less than one import-linked case following an international importation suggests that the level of population immunity is high, probably as a result of successful vaccination efforts in the United States. First-dose vaccination coverage among preschool children has been ≥90% for the past 4 years (10). Two doses of measles vaccine are required for school-aged children in 49 states (CDC, unpublished data, 2002). Sustaining high levels of vaccination is important in limiting indigenous spread of measles from imported cases and preventing measles from becoming re-established as an endemic disease in the United States.

### State-Specific Mortality from Sudden Cardiac Death — United States, 1999

Each year in the United States, 400,000–460,000 persons die of unexpected sudden cardiac death (SCD) in an emergency department (ED) or before reaching a hospital (1). Based on the latest U.S. mortality data, this report summarizes and analyzes 1999 national and state-specific SCD data. Reducing the proportion of out-of-hospital\* SCDs would decrease the overall incidence of premature death in the United States. Heart attacks are the major cause of SCD; approximately 70% of SCDs are caused by coronary heart disease. National efforts are needed to increase public awareness of heart attack symptoms and signs and to reduce delay time to treatment.

National and state mortality statistics for this report were based on data from death certificates filed in state vital statistics offices and were compiled by CDC (2). Demographic data (e.g., age and race/ethnicity) listed on death certificates were reported by funeral directors usually from information provided by the family of the decedent. Causes of death on death certificates were reported by a physician, medical examiner, or coroner. Cardiac disease death was defined as one for which the underlying cause of death was classified and coded using the International Classification of Diseases (ICD-10), Tenth Revision, for diseases of the heart (codes I00-I09, I11, I13, and I20-I51) or congenital malformations of the heart (Q20-Q24†). SCD was defined for this report as a death from cardiac disease that occurred out-of-hospital or in an ED or one in which the decedent was reported to be "dead on arrival" at a hospital. Populations at risk were defined on the basis of U.S. census bureau estimates of resident populations; age-adjusted death rates were standardized by the direct method to the 2000 projected U.S. population (3).

Among 728,743 cardiac disease deaths that occurred during 1999, a total of 462,340 (63.4%) were SCDs; 120,244 (16.5%) occurred in an ED or were dead on arrival, and 341,780 (46.9%) occurred out-of-hospital. Women had a higher total number of cardiac deaths and higher proportion of out-of-hospital cardiac deaths than men (51.9% of 375,243 and 41.7% of 353,500, respectively), and men had a higher proportion of cardiac deaths that occurred in an ED or were dead on arrival (21.2% of 353,500 and 12.0% of 375,243, respectively) (Table 1). SCDs accounted for 10,460 (75.4%) of all 13,873 cardiac disease deaths in persons aged 35-44 years, and the proportion of cardiac deaths that occurred outof-hospital increased with age, from 5.8% in persons aged 0-4 years to 61.0% in persons aged >85 years. SCDs accounted for 63.7% of all cardiac deaths among whites, 62.3% among blacks, 59.8% among American Indians/Alaska Natives, 55.8% among Asians/Pacific Islanders, and 54.2% among Hispanics. Whites had the highest proportion of cardiac deaths out-of-hospital, and blacks had the highest proportion of cardiac deaths in an ED or dead on arrival (Table 1).

<sup>\*</sup>A death that occurs in a nursing home, residence, and other unspecified place outside of a hospital.

<sup>&</sup>lt;sup>†</sup> Diseases of the heart (ICD-10 codes I00-I09, I11, I13, and I20-I51) represent certain disease types (e.g., coronary heart disease, cardiomyopathy, dysrhythmias, and conduction system disorders, hypertensive heart disease, carditis and valvular heart disease, pulmonary heart disease, and heart failure). Congenital malformations of the heart (Q20-Q24) represent other disease types (e.g., congenital malformations of cardiac chambers and connections, cardiac septa, and pulmonary, tricuspid, and aortic and mitral valves). These codes are comparable to the ICD-9 codes of 390-398, 402, 404-429, and 745-746.

<sup>\*</sup> International Classification of Disease, Tenth Revision, codes 100-109, 111, 113, 120-151, and Q20-Q24.

The age-adjusted SCD rate was 47.0% higher among men than women (206.5 and 140.7 per 100,000 population, respectively). Blacks had the highest age-adjusted rates (253.6 in men and 175.3 in women) followed by whites (204.5 in men and 138.4 in women), American Indians/Alaska Natives (132.7 in men and 76.6 in women), and Asians/Pacific Islanders (111.5 in men and 66.5 in women). Non-Hispanics (217.8 in men and 147.3 in women) had higher age-adjusted SCD rates than Hispanics (118.5 in men and 147.3 in women).

In 1999, the state-specific proportion of all cardiac deaths that was SCD ranged from 57.2% (Hawaii) to 72.9% (Wisconsin) (Table 2). Other states with a high proportion of SCDs were Idaho (72.2%), Utah (72.1%), Colorado (71.3%), Oregon (71.0%), Connecticut (70.5%), Rhode Island (70.0%), South Dakota (69.8%), Montana (69.6%), and Vermont (69.5%). Age-adjusted SCD rates (per 100,000 population) in 1999 ranged from 114.6 (Hawaii) to 212.2 (Mississippi).

Reported by: ZJ Zheng, MD, JB Croft, PhD, WH Giles, MD, CI Ayala, PhD, KJ Greenlund, PhD, NL Keenan, PhD, L Neff, PhD, WA Wattigney, M.Stat, GA Mensah, MD, Div of Adult and Community Health, National Center for Chronic Disease Prevention and Health Promotion, CDC.

**Editorial Note:** Despite advances in the prevention and treatment of heart disease and improvements in emergency transport, the proportion of cardiac deaths classified as "sudden" remains high, probably because of the unexpected nature of SCD and the failure to recognize early warning symptoms and signs of heart disease. The age-adjusted SCD rates and the state-specific variation in the proportion of SCDs suggest a need for increased public awareness of heart attack symptoms and signs. The finding that cardiac deaths out-ofhospital were more likely to occur among women than men is consistent with findings that women more often delay seeking help for heart attack symptoms (4). Early recognition of heart symptoms and signs leads to earlier artery opening treatment or defibrillation that results in less heart damage and deaths. Education and media efforts should inform the public about heart disease symptoms and signs, particularly women and young adults who might dismiss heart disease as a problem of men and the elderly (5). Health-care providers should be alert for atypical symptoms of heart disease among female and young adult patients (6).

The findings in this report are subject to at least three limitations. First, the cause of death information reported on the death certificate by the certifier is not always validated by a medical record or autopsy verification. The reliability and accuracy of the underlying cause of death also depend on the information reported by the certifier and on the state and national nosologists who determine the codes and the underlying causes. Second, because time of onset of disease symptoms and time of death are not available for analysis, the suddenness of death is determined arbitrarily and needs to be validated on the basis of clinical criteria on time frames. Third, data are subject to misclassification of race/ethnicity on death certificates, which might result in underestimating the number of deaths among American Indians/Alaska Natives, Asians/Pacific Islanders, and Hispanics and overestimating the number of deaths among blacks and whites (7).

The proportion of SCDs that occur out-of-hospital has increased since 1989 (*I*). Death and disability from a heart attack can be reduced if persons having a heart attack can immediately recognize its symptoms (8) and call 9-1-1 for emergency care. These symptoms are chest discomfort or pain; pain or discomfort in one or both arms or in the back, neck, jaw, or stomach; and shortness of breath. Other symptoms are breaking out in a cold sweat, nausea, and light headedness

<sup>&</sup>lt;sup>†</sup> Death occurred in emergency department or dead on arrival to emergency department.

<sup>\*</sup>Per 100,000 population.

† Standardized to the 2000 projected U.S. population.

§ Number too small to calculate rate.

(9). Prevention of the first cardiac event through risk factor reduction (e.g., tobacco control, weight management, physical activity, and control of high blood pressure and cholesterol intake) should continue to be the focus of public health efforts to reduce the number of deaths from heart disease. Education and systems support to promote physician adherence to clinical practice guidelines and more timely access to emergency cardiac care also are important to the prevention and early treatment of a heart attack. Prehospital emergency medical service systems can assist in reducing SCD rates by dispatching appropriately trained and properly equipped response personnel as rapidly as possible in the event of cardiac emergencies. However, national efforts are needed to increase the proportion of the public that can recognize and respond to symptoms and can intervene when someone is having a heart attack, including calling 9-1-1, attempting cardiac resuscitation, and using automated external defibrillators until emergency personnel arrive.

#### American Heart Month — February 2002

February is American Heart Month. During 2002, an estimated 1.1 million Americans will have a first or recurrent heart attack, and approximately 700,000 will die of heart disease. Among those who die, approximately 60% will die suddenly before they can reach a hospital. Recognizing and responding promptly to heart attack symptoms and receiving the appropriate artery opening treatment within 1 hour of symptom onset can prevent or limit heart damage (1). Early defibrillation within 6 minutes is the best treatment for cardiac arrest.

The American Heart Association, American College of Cardiology, state and federal agencies, and many CDC cardiovascular programs are developing and implementing activities to increase public awareness about the symptoms and signs of a heart attack. For example, during February, the Missouri state health department will promote information about heart attack symptoms at sporting events; the National Heart Attack Alert Program of the National Heart, Lung, and Blood Institute and the American Heart Association are collaborating on a nationwide heart attack education campaign, "Act in Time to Heart Attack Signs," which promotes awareness of heart attack symptoms and the formulation between patient and physician of a heart attack survival plan that emphasizes the importance of calling 9-1-1 as soon as symptoms begin (1).

Additional information is available at the American Heart Association at http://www.americanheart.org/, the American College of Cardiology at http://www.acc.org/, and the National Heart, Lung, and Blood Institute at http://www.nhlbi.nih.gov/actintime. Information about CDC's Cardiovascular Health Program and an interactive mapping of heart disease mortality at state and county levels are available at http://www.cdc.gov/nccdphp/cvd.

# Status of U.S. Department of Defense Preliminary Evaluation of the Association of Anthrax Vaccination and Congenital Anomalies

The U.S. Department of Defense (DoD), Center for Deployment Health Research at Naval Health Research Center, San Diego, used computerized medical records to conduct a preliminary evaluation of the potential association between the use of anthrax vaccine in the first trimester of pregnancy and the diagnosis of congenital anomalies in children. Review of preliminary data indicated important limitations in computerized medical records that preclude drawing conclusions from this preliminary study. Investigators are conducting a systematic evaluation of original medical records, including vaccination and infant health records. This evaluation will require several months.

Although the Food and Drug Administration-licensed vaccine has not been suspected to be a hazard to reproductive health, no studies of animals or pregnant women have been conducted, and the vaccine is neither recommended nor licensed for use in pregnancy. DoD continues to maintain a policy of avoiding anthrax vaccination of pregnant women. Because of the importance of protecting women of childbearing age from adverse health events, both military and civilian health-care providers should continue to ask women if they are pregnant or intend to become pregnant and should not vaccinate women who state that they are pregnant.

# Revision of Guidelines for the Prevention of Perinatal Group B Streptococcal Disease

CDC is revising the 1996 guidelines for the prevention of perinatal group B streptococcal disease (1) to include newly available multistate data and to address common clinical questions and challenges that have arisen during implementation of the guidelines. Comments or questions should be sent before March 15, 2002, to gbs@cdc.gov or to Group B Strep Prevention Coordinator, CDC, 1600 Clifton Road, MS C-23, Atlanta, GA 30333.

U: Unavailable. -:No reported cases.

\* Mortality data in this table are voluntarily reported from 122 cities in the United States, most of which have populations of ≥100,000. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.

† Pneumonia and influenza.

Because of changes in reporting methods in this Pennsylvania city, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks.

Total includes unknown ages.

All MMWR references are available on the Internet at http://www.cdc.gov/mmwr. Use the search function to find specific articles.

Use of trade names and commercial sources is for identification only and does not imply endorsement by the U.S. Department of Health and Human Services.

References to non-CDC sites on the Internet are provided as a service to MMWR readers and do not constitute or imply endorsement of these organizations or their programs by CDC or the U.S. Department of Health and Human Services. The Morbidity and Mortality Weekly Report (MMWR) Series is prepared by the Centers for Disease Control and Prevention (CDC) and is available free of charge in electronic format and on a paid subscription basis for paper copy. To receive an electronic copy on Friday of each week, send an e-mail message to listserv@listserv.cdc.gov. The body content should read SUBscribe mmwr-toc. Electronic copy also is available from CDC's World-Wide Web server at http://www.cdc.gov/mmwr or from CDC's file transfer protocol server at ftp://ftp.cdc.gov/pub/Publications/mmwr. To subscribe for paper copy, contact Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402; telephone (202) 512-1800.

Data in the weekly *MMWR* are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the following Friday. Address inquiries about the *MMWR* Series, including material to be considered for publication, to Editor, *MMWR* Series, Mailstop C-08, CDC, 1600 Clifton Rd., N.E., Atlanta, GA 30333; telephone (888) 232-3228.

All material in the MMWR Series is in the public domain and may be used and reprinted without permission; citation as to source, however, is appreciated.
