# Iron Deficiency — United States, 1999–2000

Iron deficiency, the most common nutritional deficiency worldwide, has negative effects on work capacity and on motor and mental development in infants, children, and adolescents, and maternal iron deficiency anemia might cause low birthweight and preterm delivery (1-3). Although iron deficiency is more common in developing countries, a significant prevalence was observed in the United States during the early 1990s among certain populations, such as toddlers and females of childbearing age (4). One of the national health objectives for 2010 is to reduce iron deficiency in these vulnerable populations by 3-4 percentage points (objective no. 19-12) (5). CDC has published recommendations to prevent iron deficiency in the United States (6). To characterize the iron status of persons in the United States, CDC calculated the prevalence of iron deficiency and iron deficiency anemia by applying a multiple-indicator model to data from the 1999– 2000 National Health and Nutrition Examination Survey (NHANES 1999-2000). These values were compared with those observed in the third National Health and Nutrition Examination Survey (NHANES III [1988-1994]) using the same multiple-indicator model. This report summarizes the results of this analysis, which indicate that iron deficiency remains 2-5 percentage points above the 2010 national health objectives. To prevent iron deficiency, vulnerable populations should be encouraged to eat iron-rich foods and breast-feed or use iron-fortified formula for infants.

Both NHANES surveys sampled the U.S. civilian, noninstitutionalized population and collected data through household interviews and physical examinations. In both surveys, blood was collected by venipuncture from all persons aged ≥1 year. Four biochemical measures of iron status were included in the analysis: hemoglobin, serum ferritin, transferrin saturation, and free erythrocyte protoporphyrin. Hemoglobin was measured in mobile examination centers in both surveys as part of a complete blood count by using an

automated electronic counter: Coulter S-Plus Jr in NHANES III and Coulter MAXM in NHANES 1999-2000 (Coulter Electronics, Hialeah, Florida). In both surveys, the remaining three iron indicators were measured at CDC by using the same assay methods and comparable quality-control materials. Serum ferritin was measured with the Bio-Rad QuantImune Ferritin IRMA<sup>TM</sup> (Bio-Rad Laboratories, Hercules, California); transferrin saturation was calculated from serum iron and total iron-binding capacity, which were measured by a modification of the automated AAII-25 colorimetric method; and free erythrocyte protoporphyrin was measured by a modification of the Sassa method (7). Because abnormal values for these iron status indicators might be caused by inflammatory conditions rather than by poor iron status (8), a serum indicator of inflammation (C-reactive protein) also was used. This indicator was measured on participants aged ≥3 years by latex-enhanced nephelometry at the University of Washington (7).

The definition of iron deficiency was an abnormal value for at least two of the following three indicators: serum ferritin, transferrin saturation, and free erythrocyte protoporphyrin. Persons with iron deficiency and a low hemoglobin value were considered to have iron deficiency anemia (4). The same threshold values to define abnormality for the four iron

## Notifiable Disease Morbidity and 122 Cities Mortality Data

Robert F. Fagan Deborah A. Adams Felicia J. Connor Lateka Dammond Patsy A. Hall Pearl C. Sharp indicators were applied to both surveys. These thresholds were derived from NHANES III (4).

The estimated prevalence of iron deficiency was greatest among toddlers aged 1–2 years (7%) and adolescent and adult females aged 12–49 years (9%–16%) (Table 1). The prevalence of iron deficiency was approximately two times higher among non-Hispanic black and Mexican-American females (19%–22%) than among non-Hispanic white females (10%). Excluding persons aged  $\geq$ 3 years with elevated C-reactive protein levels (>1 mg/dL) from the analysis did not change prevalence estimates.

The prevalence of iron deficiency was similar in NHANES III and NHANES 1999–2000 in most age and sex groups (Table 1). Exceptions included males aged 12–69 years and women aged 50–69 years; in these groups, the prevalence was substantially higher in NHANES 1999–2000 than in NHANES III as determined by a t-test (Table 1).

The prevalence of iron deficiency anemia was examined for the populations in which iron deficiency was most common in NHANES 1999–2000 (Table 2). In these groups, the prevalence was <5%, which is similar to that observed in NHANES III (Table 2).

Reported by: AC Looker, PhD, Div of Health Examination Statistics, National Center for Health Statistics; ME Cogswell, DrPH, Div of Nutrition and Physical Activity, National Center for Chronic Disease Prevention and Health Promotion; EW Gunter, MT(ASCP), Div of Laboratory Sciences, National Center for Environmental Health, CDC.

Editorial Note: Data from NHANES 1999–2000 indicate that iron deficiency anemia is uncommon in the United States, but iron deficiency remains above the 2010 objectives of 5%, 1%, and 7% for toddlers, preschool children, and females aged 12–49 years, respectively (5). Among minority females aged 12–49 years, the prevalence of iron deficiency was approximately three times greater than the 2010 national health objectives. Multiple factors, including dietary intake, parity, and socioeconomic status (4,6), might explain the continued prevalence of iron deficiency in these groups. These factors were not included in this assessment of iron status.

The findings in this report are subject to at least two limitations. First, because abnormal values for iron status indicators might reflect inflammation rather than poor iron status (8), confounding by inflammation might have affected results in some age groups. The confounding could not be addressed in toddlers because data on inflammation in this age group were not available. The confounding might have been only partially addressed in middle-aged and older adults because C-reactive protein is less sensitive for detecting chronic inflammatory conditions common in older persons than it is

<sup>\*</sup>All racial/ethnic groups.

in detecting inflammation from acute infections (9). Second, insufficient sample size also might have limited the ability to detect trends in iron deficiency over time. Data from the Pediatric Nutrition Surveillance System (PNSS) indicated that anemia continued to decline among toddlers in low-income households during the 1990s (10). Anemia is not always caused by iron deficiency, but the PNSS data suggest progress in improving iron status among children. However, the prevalence of iron deficiency did not differ substantially between the two NHANES surveys among toddlers, adolescents,

or females aged 12–49 years, possibly because of limited study power resulting from the smaller sample size in NHANES 1999–2000. For example, power calculations revealed that a sample size of approximately 1,300 would be needed in each survey to demonstrate that the difference in prevalence among females aged 16–19 years (11% versus 16%) was statistically significant. Thus, additional years of data will be needed to ascertain whether progress has been made in achieving the 2010 national health objectives for reducing iron deficiency in vulnerable populations.

Many of the adverse consequences of iron deficiency are associated with its most severe form, iron deficiency anemia (1,3). However, iron deficiency without anemia has been linked to negative impacts on cognitive development in children and adolescents (2). Continued monitoring of iron status of the U.S. population is warranted because the prevalence of iron deficiency in vulnerable populations exceeds the 2010 national health objectives.

# Usual Sources of Cigarettes for Middle and High School Students — Texas, 1998–1999

Persons often begin smoking when they are minors (aged <18 years) (1,2), and easy access to cigarettes might contribute to this behavior (3). Laws and regulations were in place in Texas during 1998-1999 to reduce minors' access to cigarettes by 1) prohibiting the sale and distribution of tobacco products to minors; 2) imposing fines against retailers caught selling cigarettes to minors; 3) prohibiting minors from purchasing, possessing, or using tobacco products; 4) limiting vending machines to adult-only locations; and 5) requiring tobacco retailers to ask for proof of identification from anyone attempting to purchase tobacco who appeared to be aged <27 years (4). To measure progress in reducing access to cigarettes among middle and high school students in Texas, CDC analyzed self-reported data from the 1998 and 1999 Texas Youth Tobacco Survey (TYTS). This report summarizes the results of that survey, which indicate that during 1998–1999, reported access to cigarettes from stores and vending machines (commercial sources) decreased among middle school students from 13.2% to 5.3% and from 7.6% to 1.7%, respectively, but access from noncommercial and other sources (e.g., stealing cigarettes and "getting them some other way") increased from 8.3% to 12.3% and from 16.6% to 23.3%, respectively. Among high school students, most sources did not change. Educating retailers and actively enforcing laws governing youth access to tobacco as part of a comprehensive tobacco-control approach are required to reduce youth access to cigarettes.

The Texas Department of Health conducted the statewide TYTS in spring 1998 and spring 1999. TYTS uses a two-stage cluster sample design to produce representative samples of public middle and high school students in Texas. The first-stage sampling included all public schools containing any grades 6–12. The probability of a school being selected depended on its enrollment size. A total of 214 schools were sampled in 1998 and 276 in 1999. At the second stage of sampling, second-period classes were selected randomly, and all students in these classes were eligible to participate. The overall response rate\* was 71.2% in 1998 and 61.0% in 1999. School participation rates decreased from a combined (middle and high school) response rate of 84.6% in 1998 to 73% for middle schools and 69.1% for high schools in 1999. Students completed an anonymous, self-administered

questionnaire that included questions on demographics, cigarette-smoking status, and sources of tobacco products. Students who reported having smoked during the 30 days preceding the survey were asked, "During the past 30 days, how did you usually get your own cigarettes?" Data were weighted to provide estimates that could be generalized to all public school students in grades 6–12 in the state. SUDAAN 7 was used to calculate standard errors for determining 95% confidence intervals (CIs).

During 1998-1999, the percentage of middle school students who smoked during the preceding 30 days and who reported buying cigarettes from a store decreased from 13.2%  $(95\% \text{ CI}=\pm 1.0)$  to  $5.3\% (95\% \text{ CI}=\pm 1.0)$ , and the percentage of those who reported buying from vending machines decreased from 7.6% (95%  $CI=\pm 1.0$ ) to 1.7% (95%  $CI=\pm 0.4$ ) (Table). A significant increase was reported among those who reported stealing cigarettes (8.3% [95% CI=±0.9] in 1998 and 12.3% [95% CI=+1.9] in 1999) or getting them in "some other way" (16.6% [95% CI=±1.2] in 1998 versus 23.3% [95% CI=±2.4] in 1999). Among high school students, no significant change was observed during 1998-1999 in the percentage who bought cigarettes from a store (33.0% [95% CI=±1.7] in 1998 and 31.1% [95% CI=±1.6] in 1999). A small but statistically significant decrease was observed in the percentage who reported buying cigarettes from vending

machines (1.8% [95% CI= $\pm$ 0.4] versus 1.0% [95% CI= $\pm$ 0.3]) in 1999. A small but statistically significant increase also was observed in the percentage who reported that "an older person" gave them cigarettes (8.0% [95% CI= $\pm$ 0.8] in 1998 and 10.5% [95% CI= $\pm$ 1.3] in 1999).

**Reported by:** P Huang, MD, C Alo, MD, D Satterwhite, Texas Dept of Health. R Caraballo, PhD, L Pederson, PhD, Office on Smoking and Health, National Center for Chronic Disease Prevention and Health Promotion; JC Zevallos, MD, EIS Officer, CDC.

**Editorial Note:** The findings in this report document a decrease in access to cigarettes from stores for middle school students in Texas and a decrease in access to cigarettes from vending machines for both middle and high school students. However, the percentages of middle school students who reported stealing cigarettes or getting them "in some other way" increased. The percentage of high school students who reported getting cigarettes from an older person also increased. These findings suggest an increase in the use of alternative sources for acquiring cigarettes (e.g., stealing or getting them from other adolescents, parents, and older friends) (5).

The findings in this report are subject to at least three limitations. First, these data apply only to youth who attend public schools in Texas and might not be representative of all persons in this age group. The average dropout rate for Texas middle and high school students during school years 1997-98 and 1998–99 was 16%, and approximately 10% of middle and high school students are enrolled in private schools (6–8). Second, the decline in school participation rates could have affected the validity of the 1998-1999 comparisons if the nonrespondents in 1999 differed from the respondents. However, given the size of some of the changes in access patterns, it is unlikely that the decrease in response rates would account for all of the changes observed. Finally, a substantial proportion of middle school students responded that they obtained tobacco products "in some other way." Future surveys should include an open-ended category to learn how students obtained tobacco products.

Studies designed to determine if reducing illegal cigarette sales to minors can reduce youth smoking prevalence suggest that substantial decreases (to as low as 3%) in illegal sales will be needed to decrease youth smoking prevalence (9). In Texas, the illegal sale rate to minors decreased from 24.0% in 1998 to 13.0% in 1999; a reduction in cigarette smoking prevalence for those years among middle school students (20.0% to 14.8%) also was observed, but not among high school

students (33.0% and 32.7%, respectively). However, it is impossible to know if the reduction in smoking prevalence among middle school students is linked directly to reductions in self-reported access to cigarettes in stores or from vending machines.

To reduce youth access to cigarettes, stricter policies prohibiting the sale of tobacco to minors are needed, and retailer and community education should be intensified. In addition, a comprehensive approach to prevent both minors and adults from using tobacco should include 1) local community programs, 2) evidence-based school programs, 3) tobacco counter marketing, 4) tobacco-use cessation programs, and 5) surveillance and evaluation systems to monitor progress in reducing the use of tobacco (10).

# Public Health Dispatch

# Vancomycin-Resistant *Staphylococcus* aureus — Pennsylvania, 2002

Staphylococcus aureus is one of the most common causes of hospital- and community-acquired infections (1,2). Since the recognition of vancomycin-resistant enterococci in 1988, the emergence of vancomycin-resistant S. aureus (VRSA) (minimum inhibitory concentration [MIC]  $\geq$ 32  $\mu$ g/mL [3]) has been anticipated. The transfer of the genetic element containing the vanA vancomycin resistance gene from Enterococcus faecalis to S. aureus was demonstrated in the laboratory in 1992 (4); the first clinical infection with VRSA was reported in July 2002 (5). This report describes the second documented clinical isolate of VRSA from a patient.

On September 20, the patient was admitted to a hospital in Pennsylvania and evaluated for a chronic foot ulcer and possible osteomyelitis. A culture of the ulcer grew S. aureus. This isolate was tested for antimicrobial susceptibility by disk diffusion; a vancomycin-agar screen plate (brain heart infusion agar containing 6 µg/mL vancomycin) also was inoculated. Growth on the vancomycin screen plate and a 12 mm zone of inhibition around the vancomycin disk suggested that the isolate had decreased susceptibility to vancomycin. Further testing by Etest® confirmed that the isolate was resistant to vancomycin (MIC=64 µg/mL). Following notification of the Pennsylvania Department of Health (PDH), the isolate was forwarded to CDC, where it was confirmed to be VRSA (vancomycin MIC=32 µg/mL by broth microdilution testing). The isolate contained both the mecA and vanA genes mediating oxacillin and vancomycin resistance, respectively. The isolate was susceptible to chloramphenicol, linezolid, minocycline, quinupristin-dalfopristin, rifampin, and trimethoprim-sulfamethoxazole.

The patient has been discharged from the hospital and is responding to antimicrobial treatment. The patient is receiving home-health care. PDH and CDC are assisting health-care providers investigating this case of VRSA. The goals of this investigation include assessment of infection-control practices in the hospital and home setting and the possibility of transmission of the organism to other patients, health-care providers, and family or social contacts. Previous investigations of VRSA and vancomycin-intermediate *S. aureus* in the home setting demonstrated no transmission among family or home health-care contacts (5,6).

The presence of *vanA* in this VRSA suggests that the resistance determinate was acquired from a vancomycin-resistant

enterococcus. Development of this VRSA appears to be unrelated to the previous VRSA identified in Michigan (5). However, because both were probably the result of conjugation events, additional VRSA infections are likely to occur. Therefore, clinical microbiology laboratories must ensure that they are using susceptibility testing methods that will detect VRSA and that they are saving potential VRSA for confirmatory testing. In addition, more systematic surveillance for VRSA will enhance the ability of the public health system and the health-care system to rapidly address this resistant pathogen.

The public health response to this VRSA occurrence is ongoing. Using proper infection-control practices and good antimicrobial agent management will help limit the emergence and spread of antimicrobial-resistant microorganisms, including VRSA. CDC recommends contact precautions when caring for patients with these infections, including placing the patient in a private room, wearing gloves and a gown during patient contact, washing hands after contact with the patient and infectious body tissues or fluids, and not sharing patient-care items with other patients. CDC guidelines for preventing spread of VRSA are available at http://www.cdc.gov/ncidod/hip/10\_20.pdf.

The isolation of *S. aureus* with confirmed or "presumptive" vancomycin resistance should be saved and reported through state and local health departments to CDC's Division of Healthcare Quality Promotion, National Center for Infectious Diseases, telephone 800-893-0485.

# West Nile Virus Activity — United States, October 3–9, 2002

This report summarizes West Nile virus (WNV) surveillance data reported to CDC through ArboNET and by states and other jurisdictions as of 8 a.m. Mountain Daylight Time, October 9, 2002.

During the reporting period of October 3–9, a total of 266 laboratory-positive human cases of WNV-associated illness were reported from Michigan (n=58), Illinois (n=55), Ohio (n=25), Pennsylvania (n=11), Alabama (n=nine), New York (n=nine), South Dakota (n=nine), Tennessee (n=nine), Texas (n=nine), Wisconsin (n=nine), Iowa (n=eight), Massachusetts (n=seven), Missouri (n=seven), Louisiana (n=six), Minnesota (n=five), Mississippi (n=five), Connecticut (n=four), Kentucky (n=four), Maryland (n=four), Virginia (n=four), Colorado (n=two), Florida (n=two), West Virginia (n=two), New Jersey (n=one), North Carolina (n=one), and Rhode Island (n=one). During this period, West Virginia and Rhode Island reported their first human WNV cases ever. Also during this time period, WNV infections were reported in 438 dead crows and 298 other dead birds. A total of 915 veterinary cases (all equine) were reported. During the same period, 136 WNVpositive mosquito pools were reported.

During 2002, a total of 2,796 human cases with laboratory evidence of recent WNV infection have been reported from Illinois (n=654), Michigan (n=401), Ohio (n=313), Louisiana (n=293), Mississippi (n=168), Indiana (n=157), Missouri (n=138), Texas (n=101), Nebraska (n=80), New York (n=60), Kentucky (n=44), Tennessee (n=40), Alabama (n=39), Pennsylvania (n=37), Iowa (n=33), South Dakota (n=33), Minnesota (n=31), Wisconsin (n=28), Virginia (n=20), Georgia (n=19), Massachusetts (n=17), North Dakota (n=15), Maryland (n=14), Arkansas (n=11), Connecticut (n=11), Florida (n=10), New Jersey (n=seven), the District of Columbia (n=six), Colorado (n=five), Oklahoma (n=four), North Carolina (n=two), West Virginia (n=two), California (n=one), Rhode Island (n=one), and South Carolina (n=one) (Figure). Among the 2,496 patients for whom data were available, the median age was 56 years (range: 1 month-99 years); 1,348 (54%) were male, and the dates of illness onset ranged from June 10 to September 26. A total of 138 human deaths have been reported. The median age of decedents was 79 years (range: 27-99 years); 82 (59%) deaths were among men. In

FIGURE. Areas reporting West Nile virus (WNV) activity — United States, 2002\*

\* As of 8 a.m. Mountain Daylight Time, October 9, 2002. † California has reported human WNV activity only.

addition, 6,071 dead crows and 4,514 other dead birds with WNV infection were reported from 43 states and the District of Columbia; 5,292 WNV infections in mammals (5,284 equines, three canines, and five other species) have been reported from 35 states (Alabama, Arkansas, Colorado, Delaware, Florida, Georgia, Illinois, Indiana, Iowa, Kansas, Kentucky, Louisiana, Maryland, Massachusetts, Minnesota, Mississippi, Missouri, Montana, Nebraska, New Jersey, New Mexico, New York, North Carolina, North Dakota, Ohio, Oklahoma, Pennsylvania, South Carolina, South Dakota, Tennessee, Texas, Vermont, Virginia, Wisconsin, and Wyoming). During 2002, WNV seroconversions have been reported in 342 sentinel chicken flocks from Florida, Iowa, Nebraska, Pennsylvania, and New York City; 4,010 WNV-positive mosquito pools have been reported from 26 states (Alabama, Arkansas, Connecticut, Delaware, Georgia, Illinois, Indiana, Iowa, Kentucky, Maryland, Massachusetts, Mississippi, Missouri, Nebraska, New Hampshire, New Jersey, New York, North Carolina, Ohio, Pennsylvania, Rhode Island, South Carolina, South Dakota, Texas, Vermont, and Virginia), New York City, and the District of Columbia.

Additional information about WNV activity is available from CDC at http://www.cdc.gov/ncidod/dvbid/westnile/index.htm and http://www.cindi.usgs.gov/hazard/event/west\_nile/west\_nile.html.

# Recommended Adult Immunization Schedule — United States, 2002–2003

Although the childhood immunization program in the United States has reduced the burden of vaccine-preventable disease substantially among children, substantial vaccinepreventable morbidity and mortality from diseases such as hepatitis A, hepatitis B, influenza, and pneumococcal infections continue to occur among adults. In February 2002, the Advisory Committee on Immunization Practices (ACIP) approved for the first time a schedule for the routine vaccination of persons aged >19 years. The Adult Immunization Schedule has been accepted by the American Academy of Family Physicians (AAFP) and the American College of Obstetricians and Gynecologists (ACOG). ACIP will review and approve annually both the recommended adult and childhood immunization schedules. Together, these schedules provide a comprehensive summary of recommendations for prevention of vaccine-preventable diseases during the life span of persons in the United States.

The Adult Immunization Schedule is based on published recommendations of ACIP (1), AAFP (2), ACOG (3), and the American College of Physicians-American Society of Internal Medicine (ACP-ASIM) with the Infectious Diseases Society of America (4) and was developed by members of these organizations and CDC. The schedule presents a tabular, color-coded summary of vaccine indications by age group (Figure 1) and medical condition (Figure 2). Footnotes included in Figure 1 are summaries of the ACIP recommendations for specific vaccines since 1991. Figure 2 includes special considerations or contraindications for vaccinating persons with specific medical conditions. Licensed combination vaccines can be used whenever any components of the combination are indicated and the vaccine's other components are not contraindicated. Providers should consult manufacturers' package inserts for detailed recommendations. CDC and ACIP will update the schedule annually through collabowith members of AAFP, ACOG, ration ACP-ASIM.

Providers should report all postvaccination reactions to the Vaccine Adverse Event Reporting System (VAERS), telephone 800-822-7967. Reporting forms and instructions on filing a VAERS report are available at http://www.vaers.org.

Tetanus-diphtheria (Td); hepatitis B; measles, mumps, and rubella (MMR); and varicella vaccines are covered by the Vaccine Injury Compensation Program (VICP). Health-care providers are required to give adult patients copies of the Vaccine Information Statements developed by CDC before administering each dose of the vaccines covered by VICP. Information on how to file a claim with VICP is available at 800-338-2382.

The schedule provides an up-to-date tool for family physicians, gynecologists, internists, and other health-care providers to assess the vaccine needs of patients during office visits and to administer the appropriate vaccines. Providers can use the schedule to promote the use of standing orders, patient-reminder/recall systems, provider-reminder systems, and other strategies that reduce missed opportunities to vaccinate their patients. The notes accompanying the age-based table and the footnotes for highlighting issues unique to chronic disease groups provide information for providers who might be unfamiliar with the dosage or contraindications of a particular vaccine.

Because adult vaccination requires the participation of health-care providers in three medical specialties (internal medicine, family practice, and obstetrics and gynecology) that do not include vaccinations in clinical training, tools such as the adult immunization schedule could play an important role in educating health-care providers who want to vaccinate their adult patients.

A printable, annotated, color version of the schedule will be available at http://www.cdc.gov/nip. Additional information on adult immunization and ordering instructions for *Increasing Adult Vaccination Rates: What Works*, a CD-ROM-based continuing education program offering primary-care providers strategies for increasing vaccination rates among their adult patients, also will be available at this website.

| For all per                    | rsons in this age group For pers  |  | tch-up on childhood vaccinations               |

\* Covered by the Vaccine Injury Compensation Program.

A primary series for adults is 3 doses: the first 2 doses administered ≥4 weeks apart and the third dose administered 6–12 months after the second dose. Administer 1 dose if the person had received the primary series and the last vaccination was ≥10 years ago. The American College of Physicians Task Force on Adult Immunization supports a second option: a single Td booster at age 50 years for persons who have completed the full pediatric series, including the teenage/young-adult booster (1).

Medical indications: chronic disorders of the cardiovascular or pulmonary systems including asthma; chronic metabolic diseases, including diabetes mellitus, renal dysfunction, hemoglobinopathies, immunosuppression (including immunosuppression caused by medications or by human immunodeficiency virus [HIV]), requiring regular medical followup or hospitalization during the preceding year; or women who will be in the second or third trimester of pregnancy during the influenza season. Occupational indications: health-care workers. Other indications: residents of nursing homes and other longterm-care facilities; persons likely to transmit influenza to persons at high risk (in-home caregivers to persons with medical indications, household contacts and out-of-home caregivers of children aged ≤23 months or children with asthma or other indicator conditions for influenza vaccination, and household members and caregivers of elderly persons and adults with high-risk conditions); and anyone who wishes to be vaccinated (2).

Medical indications: chronic disorders of the pulmonary system (excluding asthma), cardiovascular diseases, diabetes mellitus, chronic liver diseases including liver disease as a result of alcohol abuse (e.g., cirrhosis), chronic renal failure or nephrotic syndrome, functional or anatomic asplenia (e.g., sickle cell disease or splenectomy), immunosuppressive conditions (e.g., congenital immunodeficiency, HIV infection, leukemia, lymphoma, multiple myeloma, Hodgkin's disease, generalized malignancy, and organ or bone marrow transplantation), chemotherapy with alkylating agents, antimetabolites, or long-term systemic corticosteroids. Geographic/other indications: American Indian/Alaska Native. Other indications: residents of nursing homes and other long-term—care facilities (3).

\*\* Revaccination with pneumococcal polysaccharide vaccine: one-time revaccination after 5 years for persons with chronic renal failure or nephrotic syndrome, functional or anatomic asplenia (e.g., sickle cell disease or splenectomy), immunosuppressive conditions (e.g., congenital immunodeficiency, HIV infection, leukemia, lymphoma, multiple myeloma, Hodgkin's disease, generalized malignancy, and organ or bone marrow transplantation), chemotherapy with alkylating agents, antimetabolites, or long-term systemic corticosteroids. For persons aged ≥65 years, one-time revaccination if they were vaccinated ≥5 years previously and were aged <65 years at the time of primary

Medical indications: hemodialysis patients and patients who receive clotting-factor concentrates. Occupational indications: health-care workers and public-safety workers who are exposed to blood in the workplace; persons in training in schools of medicine, dentistry, nursing, laboratory technology; and other allied health professions. Behavioral indications: injection-drug users, persons with more than one sex partner during the preceding 6 months, persons with a recently acquired sexually transmitted disease (STD), all clients in STD clinics, and men who have sex with men (MSM). Other indications: household contacts and sex partners of persons with chronic hepatitis B virus (HBV) infection, clients and staff of institutions for the developmentally disabled, international travelers who will be located for >6 months in countries with high or intermediate prevalence of chronic HBV infection, and inmates of correctional facilities (4).

For the combined hepatitis A–hepatitis B vaccine, use 3 doses at 0, 1, and 6 months. *Medical indications*: persons with clotting-factor disorders or chronic liver disease. *Behavioral indications*: MSM and users of injection-drug and noninjecting illegal drugs. *Occupational indications*: persons working with hepatitis A virus (HAV)–infected primates or with HAV in a research laboratory setting. *Other indications*: persons traveling to or working in countries that have high or intermediate endemicity of hepatitis A (5).

Measles component: Adults born before 1957 might be considered to be immune to measles. Administer 2 doses of MMR for adults with at least one of the following conditions and without vaccination history:

- adults born after 1956
- persons vaccinated with killed-measles-virus vaccine during 1963-1969
- · students in postsecondary education institutions
- · health-care workers
- susceptible international travelers to countries in which measles is endemic.

Mumps component: 1 dose of MMR should be adequate for protection. Rubella component: Administer 1 dose of MMR to women whose rubella vaccination history is unreliable and counsel women to avoid becoming pregnant for 4 weeks after vaccination. For women of childbearing age, regardless of birth year, determine rubella immunity and counsel women routinely regarding congenital rubella syndrome. Do not vaccinate pregnant women or those planning to become pregnant during the next 4 weeks. If pregnant and susceptible, vaccinate as early in postpartum period as possible (6).

\*\*\* Recommended for all persons who do not have reliable clinical history of varicella infection or serologic evidence of varicella zoster virus (VZV) infection; health-care workers and family contacts of immunocompromised persons; those who live or work in environments in which transmission is likely (e.g., teachers of young children, day care employees, and residents and staff members in institutional settings); persons who live or work in environments in which VZV transmission can occur (e.g., college students, inmates and staff members of correctional institutions, and military personnel); adolescents and adults living in households with children; women who are not pregnant but who might become pregnant in the future; and international travelers who are not immune to infection. Do not vaccinate pregnant women or those planning to become pregnant during the next 4 weeks. If pregnant and susceptible, vaccinate as early in postpartum period as possible (7.8).

postpartum period as possible (7,8). Meningococcal vaccine (quadrivalent polysaccharide for serogroups A, C, Y, and W-135). Medical indications: consider vaccination for adults with terminal complement-component deficiencies or with anatomic or functional asplenia. Other indications: travelers to countries in which disease is hyperendemic or epidemic (e.g., the "meningitis belt" of sub-Saharan Africa and Mecca [Saudi Arabia] during Hajj). Revaccination at 3-5 years might be indicated for persons at high risk for infection (e.g., persons residing in areas in which disease is epidemic). Counsel college freshmen, especially those who live in dormitories, about meningococcal disease and the vaccine so that they can make an educated decision about receiving the vaccination (9). AAFP recommends that colleges should take the lead in providing education about meningococcal infection and vaccination and offer it to those who are interested. Health-care providers need not initiate discussion of the meningococcal quadravalent polysaccharide vaccine as part of routine medical care.

- Covered by the Vaccine Injury Compensation Program.
- A. If pregnancy is at second or third trimester during influenza season.
- B. Although chronic liver disease and alcoholism are not indicator conditions for influenza vaccination, administer 1 dose annually if the patient is aged ≥50 years, has other indications for influenza vaccine, or if patient requests vaccination.
- C. Asthma is an indicator condition for influenza but not for pneumococcal vaccination.
- D. For all persons with chronic liver disease.
- E. Revaccinate once if ≥5 years have elapsed since initial vaccination.
- F. Persons with impaired humoral but not cellular immunity might be vaccinated (8).
- G. Hemodialysis patients: Use special formulation of vaccine (40 μg/mL) or two 1.0 mL 20 μg doses administered at one site. Vaccinate early in the course of renal disease. Assess antibody titers to hepatitis B surface antigen (anti-HBs) levels annually. Administer additional doses if anti-HBs levels decline to <10 milliinternational units (mIU)/mL.
- H. Also administer meningococcal vaccine.
- I. Elective splenectomy: Vaccinate ≥2 weeks before surgery.
- J. Vaccinate as close to diagnosis as possible when CD4 cell counts are highest.
- K. Withhold MMR or other measles-containing vaccines from HIV-infected persons with evidence of severe immunosuppression (10).

# **National Lead Poisoning Prevention Week**

October 20–26, 2002, is National Lead Poisoning Prevention Week. Childhood lead poisoning is the most preventable environmental disease in young children, but approximately 1 million children still have elevated blood lead levels. One of the national health objectives for 2010 is to eliminate childhood lead poisoning in the United States (objective 8-11) (1). The aim of National Lead Poisoning Prevention Week is 1) to raise awareness about the importance of screening at-risk children aged 1–2 years and those aged 3–6 years who have not been previously screened and 2) to urge persons to take precautions to eliminate children's exposure to lead.

This year's theme is "Discover the Rewards of Lead-Safe Living." As part of National Lead Poisoning Prevention Week, events such as state proclamations, free lead screenings, lead-awareness community events, and educational campaigns will be conducted nationwide. CDC, the U.S. Environmental Protection Agency, and the U.S. Department of Housing and Urban Development are collaborating to coordinate activities and offer aid to local lead poisoning prevention campaigns.

Information about National Lead Poisoning Prevention Week activities is available through state or local health departments. Additional information about preventing childhood lead poisoning is available at http://cdc.gov/nceh/lead or by telephone, 800-424-5323.

# First World Report on Violence and Health

On October 3, 2002, the World Health Organization announced the release of the World Report on Violence and Health (WRVH) (1). The report is the first comprehensive review of the problem of violence on a global scale. The goals of the report are to highlight the crucial role that public health has to play in addressing the causes and consequences of violence, to make the case that violence is preventable, and to raise awareness about the problem of violence globally. The report is available at http://www5.who.int/violence\_injury\_prevention.

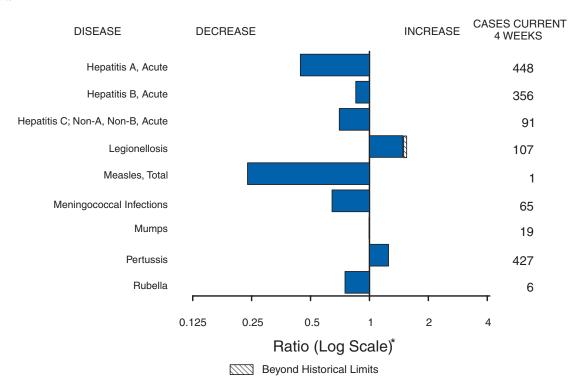

Each year, approximately 1.6 million persons die as a result of violence, and many more are injured and suffer from a range of physical, sexual, reproductive, and mental health problems. Violence is among the leading causes of death for persons aged 15–44 years worldwide, accounting for 14% of deaths among males and 7% of deaths among females (1). In the United States, violent deaths (i.e., homicide and suicide combined) are the second leading cause of death among persons in the same age group (2).

The report indicates that a science-based public health approach focused on prevention can contribute to reducing violence. The report encourages governments to develop and implement a national plan of action for violence prevention, to enhance data collection and research capacity, to promote primary prevention responses, and to strengthen emergency response systems and services for victims of violence. The report also calls for the integration of violence prevention into social and educational policies and highlights the need for mechanisms to facilitate collaboration and exchange of information on violence and its prevention among international agencies, governments, ministries of health, researchers, and civil society.

WRVH examines a broad spectrum of violence including child abuse and neglect, elder abuse, intimate partner

U: Unavailable. -: No reported cases.

Or. Orlavaliable.
 1.No reported classes.
 Mortality data in this table are voluntarily reported from 122 cities in the United States, most of which have populations of ≥100,000. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.
 Pneumonia and influenza.
 Because of changes in reporting methods in this Pennsylvania city, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks.
 Total includes unknown ages.

(Continued from page 908)

violence, sexual violence, suicide, youth violence, and collective violence (i.e., primarily armed conflict within and between states and the complex emergencies that result from such conflicts).

Additional information about child maltreatment, intimate partner violence, sexual violence, suicide, and youth violence risk factors, prevention, and new research is available at http://www.cdc.gov/ncipc.

# Erratum: Vol. 51, No. 39

In the article, "Increase in African Immigrants and Refugees with Tuberculosis—Seattle-King County, Washington, 1998–2001," on page 883, the data for the community-based TB prevention project of Seattle-King County Public Health were incorrectly attributed to the Institute of Medicine Report on TB (reference 6). The data were contributed directly from the Seattle TB prevention project.

All MMWR references are available on the Internet at http://www.cdc.gov/mmwr. Use the search function to find specific articles.

Use of trade names and commercial sources is for identification only and does not imply endorsement by the U.S. Department of Health and Human Services.

References to non-CDC sites on the Internet are provided as a service to MMWR readers and do not constitute or imply endorsement of these organizations or their programs by CDC or the U.S. Department of Health and Human Services. CDC is not responsible for the content of these sites. URL addresses listed in MMWR were current as of the date of publication.

The Morbidity and Mortality Weekly Report (MMWR) Series is prepared by the Centers for Disease Control and Prevention (CDC) and is available free of charge in electronic format and on a paid subscription basis for paper copy. To receive an electronic copy each week, send an e-mail message to listserv@listserv.cdc.gov. The body content should read SUBscribe mmwr-toc. Electronic copy also is available from CDC's World-Wide Web server at http://www.cdc.gov/mmwr or from CDC's file transfer protocol server at ftp://ftp.cdc.gov/pub/publications/mmwr. To subscribe for paper copy, contact Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402; telephone 202-512-1800.

Data in the weekly *MMWR* are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the following Friday. Address inquiries about the *MMWR* Series, including material to be considered for publication, to Editor, *MMWR* Series, Mailstop C-08, CDC, 1600 Clifton Rd., N.E., Atlanta, GA 30333; telephone 888-232-3228.

All material in the MMWR Series is in the public domain and may be used and reprinted without permission; citation as to source, however, is appreciated.
