Measles — United States, 2004

Measles is a highly infectious, acute viral illness that can cause severe pneumonia, diarrhea, encephalitis, and death. During 2004, a total of 37 cases (incidence: <1 case per million population) was reported to CDC by local and state health departments, the lowest number of measles cases ever reported in 1 year in the United States and a decrease of 16% from the previous low of 44 cases in 2002 (1). This report describes the epidemiology of measles in the United States in 2004, documenting the absence of endemic measles and the continued risk for internationally imported measles cases that can result in indigenous transmission.

Case Characteristics

Of the 37 cases, 34 (92%) were confirmed by laboratory testing (i.e., detection of measles-specific IgM antibodies or measles virus) and the remaining three (8%) were confirmed by meeting the clinical case definition (2) and by being epidemiologically linked to a laboratory-confirmed case. Confirmed measles cases occurred predominantly among preschool-aged children (aged 1-4 years), with 18 cases (49%), followed by children aged 5-19 years, with seven cases (19%), and persons aged 20-34 years and infants aged <12 months, with five cases each (14%); two cases occurred in persons aged ≥ 35 years. Three states accounted for 49% of cases: Washington (seven cases), California (six cases), and New York (five cases, including four from New York City); 11 other states reported one to three cases. No cases were reported during 32 of the 52 reporting weeks; 12 consecutive weeks was the longest period during which no cases were reported (Figure). The maximum number of reported cases occurring during a single week was four, and the median number of cases per week was one (range: zero to four cases).

FIGURE. Number of measles cases, by import status and week of rash onset — United States, 2004

Twenty-seven (73%) of the 37 cases were imported*; 14 (52%) cases occurred in U.S. residents who acquired measles while traveling abroad, and 13 (48%) occurred in foreign nationals who acquired disease abroad and traveled to the United States. The countries from which measles was imported were China (13 cases), India (four), Bangladesh (two), and Thailand (two), with six other countries contributing one case each (Malaysia, Nigeria, Philippines, Russia, Saudi Arabia, and the United Kingdom). Of the 27 persons with imported measles cases, 13 (48%) were infectious during aircraft flights

Notifiable Disease Morbidity and 122 Cities Mortality Data

Patsy A. Hall Deborah A. Adams Lenee Blanton Felicia J. Connor Rosaline Dhara Pearl C. Sharp (i.e., rash onset occurred within 4 days before through 4 days after the date of arrival). One case of transmission after exposure on an aircraft flight was documented in a passenger who had been vaccinated with 2 doses of measles-containing vaccine and who was seated next to a person with infectious disease. All 14 U.S. residents with imported cases were eligible for measles vaccination, according to recommendations from the Advisory Committee on Immunization Practices (3). Of these, nine (64%) were unvaccinated, three (21%) had unknown vaccination status, and two (14%) had been vaccinated with ≥ 1 dose of measles-containing vaccine. Of the 13 imported cases among non-U.S. residents, 10 (77%) were in unvaccinated persons and three (23%) were in persons with unknown vaccination status.

Ten (27%) of the cases were indigenous,[†] of which six (60%) were import-linked and four (40%) had unknown sources of exposure (two occurring in a two-case chain of transmission and two sporadic cases with no epidemiologic link to any other measles case). Eight (80%) cases occurred in vaccine-eligible persons (i.e., aged \geq 12 months and born after 1957); of these, five (63%) persons were unvaccinated, one (13%) had unknown vaccination status, and two (25%) had been vaccinated.

Outbreaks

During 2004, two measles outbreaks, defined as three or more epidemiologically linked cases, were reported to CDC. These outbreaks occurred in five states and accounted for 13 (35%) of the 37 cases. In one outbreak, nine children aged 12–18 months who acquired disease while in orphanages in China traveled as adoptees to three states (Maryland, New York, and Washington). One case of secondary spread was identified in a California resident aged 19 years with a nonmedical exemption for measles vaccination who had had close contact with one of the adoptees (4). In the second outbreak, a U.S. student aged 19 years with a nonmedical exemption for measles vaccination was infected in India and returned to Iowa, where two secondary cases occurred: one in an unvaccinated close contact of the index patient and one in a person who had been seated next to the index patient on an aircraft (5).

[†] Indigenous cases are those in persons infected in the United States. Indigenous cases are classified into three groups: import-linked (i.e., epidemiologically linked to an imported case); imported virus (i.e., cases that cannot be linked epidemiologically to an imported case but for which imported virus has been isolated from the patient or from an epidemiologically linked patient); and unknown source (i.e., all other cases acquired in the United States for which no epidemiologic link or virologic evidence indicates importation).

Viral Genotypes

Three genotypes of measles virus were identified among viral samples collected from nine patients. D8, a genotype found in South Asia, was identified from cases in the outbreak arising from the U.S. traveler returning from India, a two-case chain of transmission resulting from travel of the index patient from India, and a single case imported from Bangladesh. Genotype H1, endemic in East Asia, was detected from cases in the outbreak traced to adoptees from China and from an unrelated two-case chain of transmission involving an adoptee from China. Virus isolated from a single case imported from the Philippines was determined to belong to genotype D3.

Reported by: G Dayan, MD, S Redd, C LeBaron, MD, Epidemiology and Surveillance Div, National Immunization Program; P Rota, PhD, J Rota, MPH, W Bellini, PhD, Div of Viral and Rickettsial Diseases, National Center for Infectious Diseases, CDC.

Editorial Note: The 37 confirmed cases in 2004 represent a record low number of reported measles cases since measles became a nationally reportable disease in 1912. The epidemiology of measles in 2004 confirms the previous finding that endemic transmission of measles virus has been eliminated in the United States (6). Thirty-three (89%) cases were importassociated (i.e., imported or import-linked), and 14 imported cases occurred among U.S. residents who contracted measles while traveling abroad. Sixty-four percent of the imported cases among U.S. residents could have been prevented if long-standing ACIP recommendations concerning measles vaccination of foreign travelers (3) had been followed.

Of the 27 persons with imported cases in 2004, 13 (48%) traveled on aircraft while infectious. Measles virus is a highly infectious pathogen, and intercontinental flights create the potential for prolonged exposure. However, on the basis of available data, the risk for in-flight measles transmission among passengers appears to be low (7). Of the hundreds of persons on the same flights as the 13 persons who traveled while infectious in 2004, only one case of secondary transmission was identified, in a person seated immediately next to an infectious passenger. For the 8-year period (1996-2004) for which such transmission data have been recorded, 117 passengers with imported measles cases were considered infectious while traveling by aircraft (carrying an estimated 10,000 passengers), but only four secondary-spread cases were identified from three index patients (CDC, unpublished data, 1996-2004). Seating location was recorded for two of the three index patients, both of whom were seated immediately adjacent to the secondary-spread patients. The low in-flight attack rate might be related to high vaccination/immunity levels among persons traveling by air (most of whom are adults)

and to vertical airflow patterns within airplanes, which might decrease in-flight exposure to measles.

As long as measles is endemic in most countries worldwide, sustaining measles elimination in the United States will require maintenance of high levels of vaccination coverage (i.e., >90%) (8), vigilance in detecting and containing imported cases, and enhanced surveillance to detect and characterize cases and identify sources and viral genotypes.

Acknowledgments

This report is based, in part, on data contributed by state and local health departments.

Late Relapse of *Plasmodium* ovale Malaria — Philadelphia, Pennsylvania, November 2004

Approximately 1,300 cases of malaria are reported each year in the United States; nearly all of these cases occur in travelers, many of whom fail to receive or adhere to prescribed chemoprophylaxis or do not follow recommendations for prevention of mosquito bites. Malaria can persist if not treated or if treated incorrectly (e.g., with an ineffective drug or an incorrect dosage of an effective drug) (1). Early treatment is required to avoid severe illness or death. Although malaria typically becomes clinically apparent within 1 month of infection, cases can occur years after the last presumed exposure. In November 2004, CDC received a report of a late relapse of malaria in a Nigerian man aged 23 years in Philadelphia, Pennsylvania. His malaria was determined to have been caused by *Plasmodium ovale*, one of the four species of *Plasmodium* parasite that are transmitted by mosquitoes and cause malaria. The patient had been treated for malaria in Nigeria on multiple occasions, most recently 6 years before onset of his illness in the United States. This report describes the Philadelphia case, which underscores the importance of taking a detailed travel and immigration history when evaluating unexplained fever and considering malaria in the differential diagnosis.

Case Report

The man sought care at a hospital emergency department after 10 days of nocturnal fevers, chills, and night sweats, occurring every 48–72 hours. He had a history of identical symptoms that had been treated empirically as presumed malaria, a common practice with patients with unexplained fever in malaria-endemic areas with limited diagnostic capabilities; no laboratory tests had been performed in Nigeria to confirm this diagnosis, the most recent of which was made 6 years earlier. The patient did not recall which medications he had received. The patient said he had no unexplained episodes of fever during the 4 years since immigrating to the United States and no recent travel to Nigeria or any other area where malaria is endemic; moreover, the patient said he had not traveled outside of the Philadelphia area since immigrating.

The patient was afebrile in the emergency department. Physical examination was normal; the liver and spleen were not palpable. Laboratory work was notable only for hemoglobin of 12.8 g/dL (normal range: 14–18 g/dL) and total bilirubin of 5.0 mg/dL (normal: <1.5 mg/dL), with direct bilirubin of 0.4 mg/dL (normal range: 0–0.3 mg/dL). A peripheral blood film revealed *P. ovale* (0.2% of red blood cells infected). These blood-film results subsequently were confirmed at CDC.

The patient was admitted to the hospital for less than 2 hours and then discharged with a treatment regimen of 7 days of quinine and doxycycline; he was not administered chloroquine, the treatment of choice for *P. ovale* infection, because none was available at the hospital pharmacy and the regimen prescribed was an appropriate immediate alternative. His symptoms resolved within 48 hours. Subsequently, a screen for glucose-6-phosphate dehydrogenase (G6PD) deficiency was negative (a requirement for primaquine), and a 14-day course of primaquine (30 mg daily) was administered. After 4 months, the patient reported no further symptoms.

Reported by: J Rubinstein, MD, Thomas Jefferson Univ/Frankford Torresdale Campus; RA Fischer, MD, Albert Einstein Medical Center, Philadelphia, Pennsylvania. RD Newman, MD, ME Parise, MD, SP Johnston, MS, J Young, MS, Div of Parasitic Diseases, National Center for Infectious Diseases, CDC.

Editorial Note: Malaria is caused by any of the four species of Plasmodium (P. falciparum, P. vivax, P. ovale, or P. malariae) parasite transmitted by the bite of an infective female Anopheles mosquito. Nearly all malaria cases in the United States occur among persons who have traveled to areas with ongoing transmission. Infections also can be acquired locally through exposure to infected blood products, by congenital transmission, or by local mosquito-borne transmission. Treatment decisions take into account the infecting Plasmodium species, percentage of red blood cells infected, likely geographic origin of the infection, and clinical status of the patient (2). With P. ovale and P. vivax infections, certain parasites can remain dormant in the liver (i.e., hypnozoites) before infecting red blood cells and causing a relapse, even after appropriate treatment of a blood-stage infection. Fewer relapses occur with *P. ovale* malaria than with *P. vivax* (3).

Malaria caused by *P. ovale* is the least common malaria reported in the United States, accounting for only 2.6% of cases in 2003 (1). However, in Nigeria, malaria caused by *P. ovale* is second only to *P. falciparum* in frequency. In one clinical study of U.S. cases of *P. ovale*, relapses occurred 17–255 days after the primary attack (4). Other reports describe a relapse occurring 45 months after treatment of the primary attack of *P. ovale*, (5) and transmission of *P. ovale* from a blood donor exposed 7 years before donation (6).

The case described in this report highlights the importance of taking a complete travel and immigration history from persons with unexplained febrile illnesses. The history should include all foreign travel, immigration details, and any history of malaria, including whether or not the malaria was laboratory confirmed. Primaquine, the only available drug that kills hypnozoites, is used to clear the liver of *P. ovale* and *P. vivax* hypnozoites and thereby prevent malaria relapses. When primaquine is administered presumptively in conjunction with a blood-stage prophylactic agent to prevent a possible P. vivax or *P. ovale* relapse, this therapy is called terminal prophylaxis or presumptive antirelapse therapy (PART) (7). Primaquine used in conjunction with an effective drug for killing bloodstage parasites (i.e., schizonts) in a patient with P. vivax or P. ovale malaria is called radical cure. PART and radical cure are the current strategies for preventing P. vivax and P. ovale relapses (7).

CDC recommends a primaquine phosphate dose of 30 mg (base) by mouth daily for 14 days. Primaquine must not be used during pregnancy because it can cross the placenta and cause hemolysis in a G6PD-deficient fetus. Because of the risk for hemolysis from primaquine, patients must be screened

for G6PD deficiency before starting treatment. For persons with G6PD deficiency, radical cure options should be reviewed with a specialist in infectious disease or tropical medicine. Primaquine is not recommended for PART in persons with G6PD deficiency (7).

Health-care practitioners should consider malaria in their differential diagnoses of patients who have unexplained fever and 1) have a history of malaria, 2) have lived in a malariaendemic country, or 3) have traveled to a malaria-endemic country. A malaria blood film should be performed and appropriate treatment administered. Current guidelines for the diagnosis and treatment of malaria are available at http:// www.cdc.gov/malaria.

Outbreak of Cutaneous Bacillus cereus Infections Among Cadets in a University Military Program — Georgia, August 2004

Although *Bacillus cereus* is known mainly as an agent of food poisoning, other infections caused by this organism have been documented in immunocompromised patients, including sepsis, meningitis, pneumonia, and wound infections (1,2). Certain populations are at increased risk for *B. cereus* infection, including cancer patients, neonates, intravenous drug users, and patients with a history of trauma, surgery, or catheterization (3–6). Primary cutaneous disease attributed to *B. cereus* in immunocompetent persons or in non–health-care settings rarely has been reported (7). This report is the first to document such an outbreak. On August 24, 2004, a local health department in Georgia received a call from a university health center describing 90 cadets with nonpruritic, impetigo-like lesions on their scalps; B. cereus was the common organism among the three patients whose lesions were cultured. The cases occurred during the freshman military orientation week that preceded the start of the fall term. The Georgia Division of Public Health (GDPH) conducted an investigation to determine the source of the infections, identify associated risk factors, and implement control measures. This report summarizes the results of the outbreak investigation, which identified receiving a short haircut at the start of orientation week, sharing sunscreen during the week, and membership in Company B as strongly associated with having scalp lesions. Recommendations to the university included changing the type of haircut required, increasing time allowed for showering, and issuing individual sunscreen. The results of this investigation underscore the need for military programs to incorporate good hygiene and infection-control measures into school orientation events.

GDPH reviewed the events of orientation week, investigated cases of scalp dermatitis, collected environmental samples, and conducted a cohort study of participants in the military program during four site visits to the university. University personnel provided a schedule of orientation activities and a tour of each event location. Medical records from patients were reviewed and clinical findings discussed with university health-care staff. Patients were interviewed, and available clinical isolates were sent to the Georgia Public Health Laboratory for confirmation. Samples, including talc, Barbicide[®] disinfectant, and swabs of electric clippers, were collected from two barbershops providing haircuts to cadets. Soil and water samples were collected from event sites, and swabs were taken of shared helmets and sunscreen. Five patients donated their hats for the environmental and laboratory investigation. CDC analyzed the environmental samples and characterized bacterial isolates by biochemical analysis, 16S rRNA gene sequencing (8), and multilocus sequence typing (MLST) (9).

After the initial investigation, GDPH conducted a cohort study of all cadets in the military program at the university. GDPH distributed questionnaires to all 660 cadets, including upperclassmen, 3 weeks after orientation week. The cadets were asked about demographic information, company and dormitory assignment, clinical symptoms, orientation event participation, exposure to soil and water, and hygiene practices, including laundry, bathing, and shared products. A case was defined as an occurrence of scalp lesions in a cadet treated with oral cephalexin from the school health center during August 10–30, 2004. Measures of association were estimated using multivariate logistic regression to control for confounding.

The 4-year military program at the university had 660 students (292 freshman and 368 upperclassmen) organized into seven discrete companies. Cadets lived in five separate dormitories, two per room, organized by company, sex, and class year. Each floor shared a bathroom and a common living room. Orientation directly involved 292 freshmen; 115 upperclassmen supervised the events. Orientation started with a short haircut for all 255 freshman males at one of two civilian barbershops. Haircuts were performed by one of eight barbers in random order using electric clippers without a scalp guard. The third day of orientation week, the cadets completed an obstacle course involving immersion in mud and river water. On the final day, participants were required to rappel from rock walls and participate in survival training exercises. Helmets were worn and sunscreen was shared among cadets during these activities.

Ninety-four (14%) of 660 cadets had scalp lesions, and one cadet was infected twice during the period from the start of orientation to when the questionnaire was administered. Thirty-three patients sought care at the student health center on the fourth day of orientation week, and 57 sought care on the fifth day. Five more cases, including the recurrent case, occurred 1 week after the start of school (Figure). All patients participated in orientation week; all were male and ranged in age from 16 to 24 years. The majority of patients were freshmen (84/94; 89%) and received a haircut on the first day of orientation (89/94; 95%). Approximately one third of the patients (33/94; 35%) were in Company B.

The index patient noted onset of symptoms on the third day of orientation. Yellow sticky discharge followed by honeycolored crusts on the crown of his head were noted. Lesions were nonpruritic. Other patients had similar lesions with the

FIGURE. Number* of university military program cadets with scalp lesions, by date of diagnosis — Georgia, August 13–25, 2004

*N = 94. One recurrent case occurred on August 23, and two on September 20, 2004.

same distribution. Infections resolved within 48 hours with the use of antibacterial soap and oral cephalexin (5-day prescription). Health-care providers obtained samples for culture from lesions of three cadets (Table). B. cereus was the only common organism isolated from all three patients and was identified by using biochemical tests and 16S rRNA gene sequencing. When analyzed by MLST, all three clinical *B. cereus* isolates were indistinguishable. B. cereus also was cultured from two separate barbershop clippers (two isolates), soil from the school grounds and orientation events (five isolates), and helmets (two isolates) worn during rappelling exercises. Five environmental isolates (three soil samples and two clippers) matched the clinical isolates by 16S rRNA. MLST was performed on these isolates, resulting in four unique sequence types (three from the soil samples and one from the two clippers), with no matches to the clinical *B. cereus* sequence type.

The response rate for the cohort study was 73% (483/660); the response rate for freshmen was 84% (248/292). Of the respondents, 423 (88%) were male, and 248 (51%) were freshmen, which was representative of the entire cohort. The median age was 19 years, and 405 (84%) cadets were white. After adjusting for sex, freshman class status, and participation in orientation week, the multivariate logistic regression model indicated a statistically significant association between having scalp lesions and receiving a haircut (adjusted odds ratio [AOR] = 10.6; 95% confidence internal [CI] = 2.3–49.3, p<0.01), membership in Company B (AOR = 9.7; CI = 3.4–27.8, p<0.01). Other risk factors examined included demographic information, exposure to soil and water, and hygiene practices (e.g., laundry, bathing, and use of shared products).

MJ Arduino, DrPH, J Noble-Wang, PhD, Div of Healthcare Quality Promotion; A Hoffmaster, PhD, JE Gee, PhD, P Wilkins, PhD, J Jordan, R Morey, M Daneshvar, PhD, Div of Bacterial and Mycotic Diseases, National Center for Infectious Diseases; C Shuler, DVM, EIS Officer, CDC.

Editorial Note: *Bacillus cereus* is a recognized bacterial pathogen in humans. Nongastrointestinal infections are usually the result of a breakdown in natural protective barriers such as the skin or immune system (1,2,5). The findings in this

TABLE. Positive scalp bacterial culture results for three university military program cadets, by date and organism — Georgia, August 2004

1235

report indicate that immunocompetent persons can be vulnerable to cutaneous *B. cereus* infections when skin is compromised. Isolation of three indistinguishable *B. cereus* isolates from three patients on two separate days suggested that this was a common-source outbreak and not a laboratory contaminant, even though the environmental source of *B. cereus* was not identified during the investigation. All but five cases were diagnosed on two concurrent days, making person-toperson transmission unlikely. Transmission most likely occurred from an exposure at the beginning of the orientation week. The short haircut likely caused microabrasions, compromising the protective effect of scalp epidermis. Exposure to mud, sun, and sunscreen further provided an environment suitable for bacterial growth.

The findings in this report are subject to at least three limitations. First, only three clinical samples were available for culture. Because of the number of cases and the positive response to therapy, the health-center staff treated cases empirically before GDPH involvement. Second, other risk factors and potential confounders might not have been identified during the site visits. Finally, cadets were asked about their orientation exposures nearly 3 weeks after the events occurred; recall bias might have influenced the findings.

As a result of this investigation, GDPH made recommendations to the university military program for future orientations to minimize the risk for another outbreak. These included 1) changing the type of haircut required for male cadets that would allow for more hair and less injury to the scalp, 2) allowing adequate time for personal hygiene, and 3) distributing individual packets of sunscreen and discouraging sharing of sunscreen. These recommendations were implemented during the 2005 orientation activities; no skin infections were reported. University military programs should establish infection-control practices including good hygiene as part of their organized orientation events.

Acknowledgments

The findings in this report are based, in part, on contributions from P Blake, MD, M Tobin-D'Angelo, MD, Georgia Div of Public Health.

Notice to Readers

FDA Approval of Havrix® (Hepatitis A Vaccine, Inactivated) for Persons Aged 1–18 Years

On October 17, 2005, the Food and Drug Administration approved an application to allow use of the pediatric/adolescent formulation of Havrix[®] (hepatitis A vaccine, inactivated) (GlaxoSmithKline Biologicals, Rixensart, Belgium) for persons aged 1–18 years. Previously, pediatric use of Havrix was approved for use in persons aged 2–18 years.

Vaccine Description

The formulation, dosage, and schedule for Havrix were not changed. Each 0.5-mL dose of pediatric/adolescent Havrix contains 720 enzyme-linked immunosorbent assay units of formalin-inactivated hepatitis A viral antigen adsorbed onto aluminum hydroxide. The formulation contains 0.5% 2-phenoxyethanol as a preservative.

The pediatric/adolescent formulation of Havrix is indicated for vaccination of persons aged 1–18 years against disease caused by hepatitis A virus. Recommendations for hepatitis A vaccination have been published previously (1) and are periodically updated. The primary vaccination schedule is unchanged and consists of 2 doses, administered on a 0, 6-12-month schedule.

In a study presented as part of the labeling change application, 99% of 218 children aged 11–13 months and 100% of 200 children aged 15–18 months who received 2 doses of Havrix developed a vaccine response. The approval included concomitant use of Havrix with *Haemophilus influenzae* type b conjugate vaccine (PRP-T Hib). Data regarding concomitant use with other routinely recommended childhood vaccines are limited. According to general recommendations of the Advisory Committee on Immunization Practices, inactivated vaccines usually do not interfere with the immune response to other inactivated or live vaccines (2). Among the 723 healthy children who received 1 or more dose of Havrix, the most common adverse events were similar among children aged 11–18 months and children aged 23– 25 months. Havrix is contraindicated in persons with known hypersensitivity to any component of the vaccine. Additional information is available from the manufacturer's package insert and GlaxoSmithKline Biologicals at telephone 888-825-5249.

Notice to Readers

Epidemiology in Action Course

The Rollins School of Public Health at Emory University and CDC will cosponsor a course, Epidemiology in Action, March 27–April 7, 2006 at Emory University. The course is designed for state and local public health workers.

The course emphasizes the practical application of epidemiology to public health problems and will consist of lectures, workshops, classroom exercises (including actual epidemiologic problems), and roundtable discussions. Topics include descriptive epidemiology and biostatistics, analytic epidemiology, epidemic investigations, public health surveillance, surveys and sampling, Epi Info (Windows version) training, and discussions of selected prevalent diseases. Tuition is charged.

Additional information and applications are available from Emory University, Rollins School of Public Health, Global Health Dept (Pia), 1518 Clifton Rd. NE, Rm. 746, Atlanta, GA 30322; by telephone, 404-727-3845; by fax, 404-727-4590; online at http://www.sph.emory.edu/epicourses; or by e-mail, pvaleri@sph.emory.edu.

Epidemiology in Action: Intermediate Methods

CDC and Emory University's Rollins School of Public Health will co-sponsor a course, Epidemiology in Action: Intermediate Methods, February 27–March 3, 2006, at Emory University. The course is designed for practicing public health professionals who have had training and experience in basic applied epidemiology and desire training in additional quantitative skills related to analysis and interpretation of epidemiologic data.

The course includes a review of the fundamentals of descriptive epidemiology and biostatistics, measures of association, normal and binomial distributions, confounding, statistical tests, stratification, logistic regression, models, and computers as used in epidemiology.

Prerequisite is an introductory course in epidemiology, such as Epidemiology in Action, the International Course in Applied Epidemiology, or any other introductory class. Tuition is charged. Application deadline is January 27, 2006.

Additional information and applications are available from Emory University, Rollins School of Public Health, Global Health Dept (Pia), 1518 Clifton Rd. NE, Rm. 746, Atlanta, GA 30322; by telephone, 404-727-3845; by fax, 404-727-4590; online at http://www.sph.emory.edu/epicourses; or by e-mail, pvaleri@sph.emory.edu.

Epi Info: A Course to Develop Public Health Software Applications

CDC and Emory University's Rollins School of Public Health will cosponsor "Epi Info: A Course to Develop Public Health Software Applications" on March 13–15, 2006, at Emory University. The course is designed for practitioners of epidemiology and computing with intermediate-to-advanced computer skills who wish to develop public health software applications using Epi Info for Windows 98, NT, 2000, and XP.

The 3-day course covers hands-on experience with the new Windows version of Epi Info, programming Epi Info software at beginning-to-intermediate level, and computerized interactive exercises for developing public health information systems. All Epi Info modules, such as Makeview, Checkcode, Enter, Analysis, Epi Map, and Epi Report, will be covered. Tuition is charged.

Additional information and applications are available from Emory University, Rollins School of Public Health, Global Health Dept (Pia), 1518 Clifton Rd. NE, Rm. 746, Atlanta, GA 30322; by telephone, 404-727-3845; by fax, 404-727-4590; online at http://www.sph.emory.edu/epicourses; or by e-mail, pvaleri@sph.emory.edu.

Errata: Vol. 54, No. 47

In the Notice to Readers, "Licensure of a Combined Live Attenuated Measles, Mumps, Rubella, and Varicella Vaccine," multiple errors occurred.

On page 1212, in the last sentence of the first paragraph, the sentence should read: The titer of Oka/Merck varicellazoster virus is higher in MMRV vaccine than in single antigen varicella vaccine, VARIVAX[®] (Merck), a minimum of **3.99** \log_{10} plaque-forming units (pfu) versus 1,350 pfu (approximately **3.13** \log_{10}), respectively. On page 1213, under "Indications and Usage," No. 1, the last sentence should read: MMRV vaccine can reduce the number of injections when administered to children aged 12 months–12 years for whom 1) the first doses of MMR and varicella vaccines **are** indicated and 2) the second dose of MMR and either the first or second dose (e.g., during a varicella outbreak) of varicella vaccine **are** indicated. MMRV vaccine is administered subcutaneously as a single 0.5-mL dose.

On page 1214, in Reference 8, the Internet address should read: http://www.cdc.gov/nip/vaccine/varicella/varicella_acip_recs.pdf.

During 2003, an estimated 906 million visits were made to physician offices in the United States, approximately 3.2 visits per person overall. Infants aged <1 year and adults aged \geq 65 years were the most frequent visitors, with approximately 6.6 visits per person in each of those age groups.

FIGURE I. Selected notifiable disease reports, United States, comparison of provisional 4-week totals December 3, 2005, with historical data

Ratio (Log scale)[†]

Beyond historical limits

No measles cases were reported for the current 4-week period yielding a ratio for week 48 of zero (0).

[†] Ratio of current 4-week total to mean of 15 4-week totals (from previous, comparable, and subsequent 4-week periods for the past 5 years). The point where the hatched area begins is based on the mean and two standard deviations of these 4-week totals.

U: Unavailable. -: No reported cases.

*Mortality data in this table are voluntarily reported from 122 cities in the United States, most of which have populations of ≥100,000. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.

[†]Pneumonia and influenza.

[§] Because of changes in reporting methods in this Pennsylvania city, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks. [¶]Because of Hurricane Katrina, weekly reporting of deaths has been temporarily disrupted.

** Total includes unknown ages.

The Morbidity and Mortality Weekly Report (MMWR) Series is prepared by the Centers for Disease Control and Prevention (CDC) and is available free of charge in electronic format and on a paid subscription basis for paper copy. To receive an electronic copy each week, send an e-mail message to *listserv@listserv.cdc.gov*. The body content should read *SUBscribe mmwr-toc*. Electronic copy also is available from CDC's World-Wide Web server at *http://www.cdc.gov/mmwr* or from CDC's file transfer protocol server at *ftp://ftp.cdc.gov/pub/publications/mmwr*. To subscribe for paper copy, contact Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402; telephone 202-512-1800.

Data in the weekly *MMWR* are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the following Friday. Address inquiries about the *MMWR* Series, including material to be considered for publication, to Editor, *MMWR* Series, Mailstop K-95, CDC, 1600 Clifton Rd., N.E., Atlanta, GA 30333; telephone 888-232-3228.

All material in the MMWR Series is in the public domain and may be used and reprinted without permission; citation as to source, however, is appreciated.

All MMWR references are available on the Internet at http://www.cdc.gov/mmwr. Use the search function to find specific articles.

Use of trade names and commercial sources is for identification only and does not imply endorsement by the U.S. Department of Health and Human Services.

References to non-CDC sites on the Internet are provided as a service to *MMWR* readers and do not constitute or imply endorsement of these organizations or their programs by CDC or the U.S. Department of Health and Human Services. CDC is not responsible for the content of these sites. URL addresses listed in *MMWR* were current as of the date of publication.
